

# CH643 Reference Manual

V1.7

<https://wch-ic.com>

## Overview

CH643 is an industrial-grade RGB display driver microcontroller based on the QingKe V4C core, with built-in USB and PD PHY, supporting USB Host and USB Device, USB PD and type C fast charging, PWM driven RGB LED, built-in programmable protocol I/O controller (PIOC), providing 2 OPAs, 3 CMPs, 4 USARTs, I2C, SPI, multiple timers, 12-bit ADC, 15 touch-key, etc.

This manual provides detailed information on the use of the CH643 product for the user's application development.

Please refer to the following datasheet for device characteristics of this family: *CH643DS0*.

For information about the RISC-V core, please refer to the following: *QingKeV4\_Processor\_Manual*.

### RISC-V core version comparison overview

| Core versions | Features<br>Instruction set | Hardware stack levels | Interrupt nesting levels | Fast interrupt channels | Integer division cycles | Vector table model | Extended instruction | Memory protection |
|---------------|-----------------------------|-----------------------|--------------------------|-------------------------|-------------------------|--------------------|----------------------|-------------------|
| QingKeV4B     | IMAC                        | 2                     | 2                        | 4                       | 9                       | Address or command | Supported            | None              |

**Abbreviated description of the bit attribute in the register:**

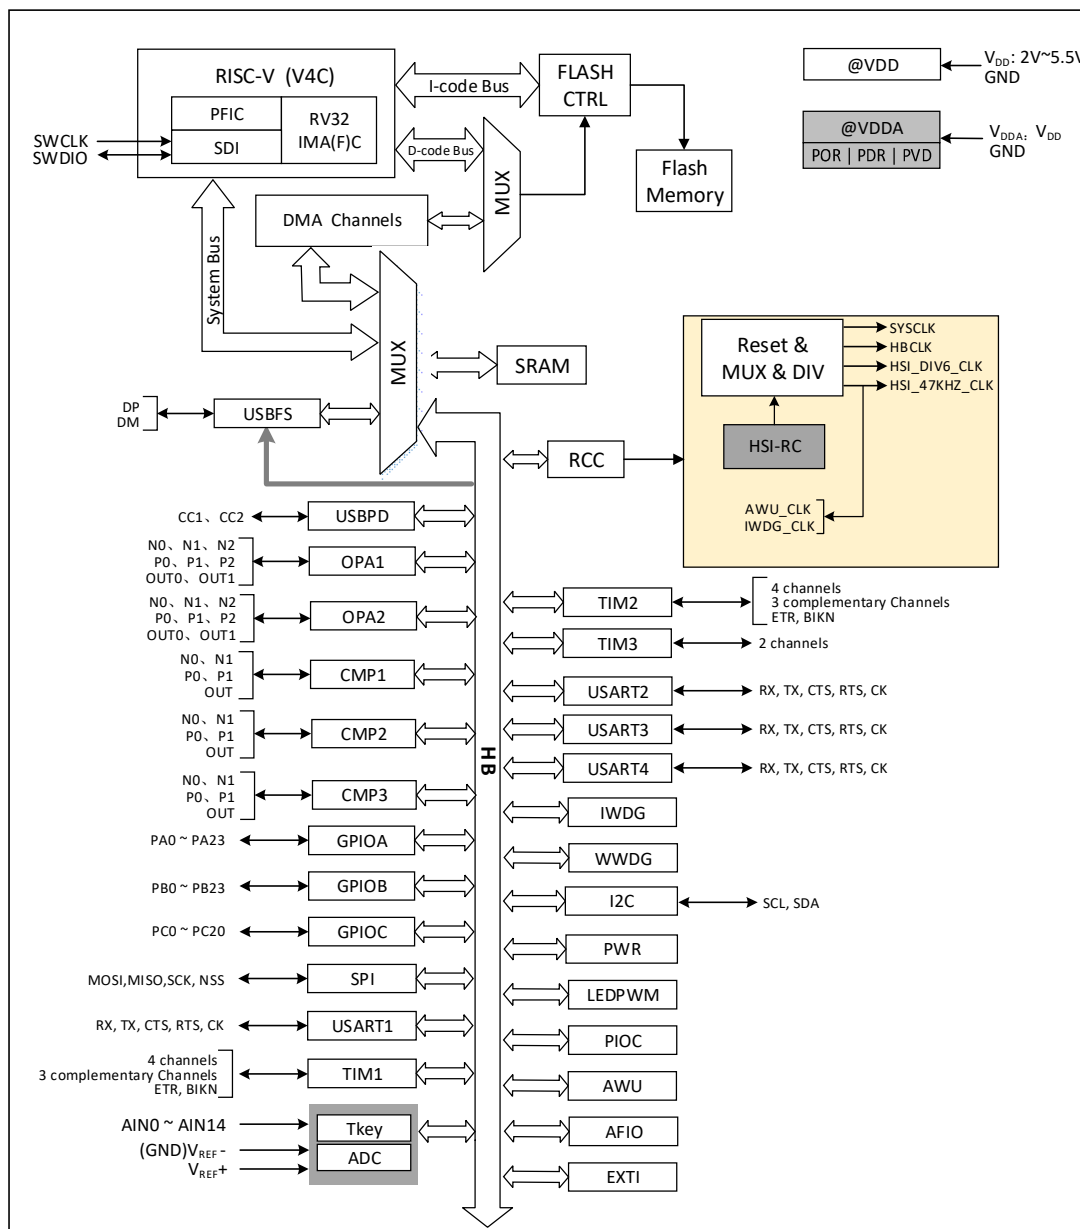

| <b>Register bit attributes</b> | <b>Property description</b>                                   |
|--------------------------------|---------------------------------------------------------------|
| RF                             | Read-only attribute, read a fixed value.                      |
| RO                             | Read-only attribute, changed by hardware.                     |
| RZ                             | Read-only attribute, auto bit clear 0 after read operation.   |
| WO                             | Write only attribute (Not readable, read value uncertain)     |
| WA                             | Write-only attribute, writable in Safe mode.                  |
| WZ                             | Write only attribute, auto bit clear 0 after write operation. |
| RW                             | Readable and writable.                                        |
| RWA                            | Readable, writable in Safe mode.                              |
| RW1                            | Readable, write 1 valid, write 0 invalid.                     |
| RW0                            | Readable, write 0 valid, write 1 invalid.                     |
| RW1T                           | Readable, write 0 invalid, write 1 flipped.                   |
| SC                             | Auto cleared.                                                 |

# Chapter 1 Memory and Bus Architecture

## 1.1 Bus Architecture

The microcontroller is designed on the basis of the RISC-V instruction set and its architecture incorporates QingKe microprocessor core, arbitration unit, DMA module, SRAM storage and other components interacting via multiple sets of buses. Its system block diagram is shown in Figure 1-1.

Figure 1-1 CH643 system block diagram

The system is equipped with: General-purpose DMA controller to reduce the CPU burden and improve efficiency; clock tree hierarchy management to reduce the total power consumption of peripherals, as well as data protection mechanisms, clock security system protection mechanisms and other measures to increase system stability.

- The instruction bus (I-Code) connects the core to the FLASH instruction interface and prefetching is done on this bus.
- The data bus (D-Code) connects the core to the FLASH data interface for constant loading and debugging.

- The system bus connects the core to the bus matrix and is used to coordinate accesses to the core, DMA, SRAM and peripherals.
- The DMA bus is responsible for the DMA of the HB master interface connected to the bus matrix, which is accessed by FLASH data, SRAM and peripherals.
- The bus matrix is responsible for the access coordination between the system bus, data bus, DMA bus, SRAM and HB bridge.

access.

Built-in up to 62KB program Flash memory (CodeFlash) for storing user applications.

Built-in 3328B System memory (Bootloader) for storing the system bootloader (Factory-cured bootloader).

Built-in 256B space for vendor configuration word storage, factory-cured and unmodifiable by users.

Built-in 256B space for user option byte storage.

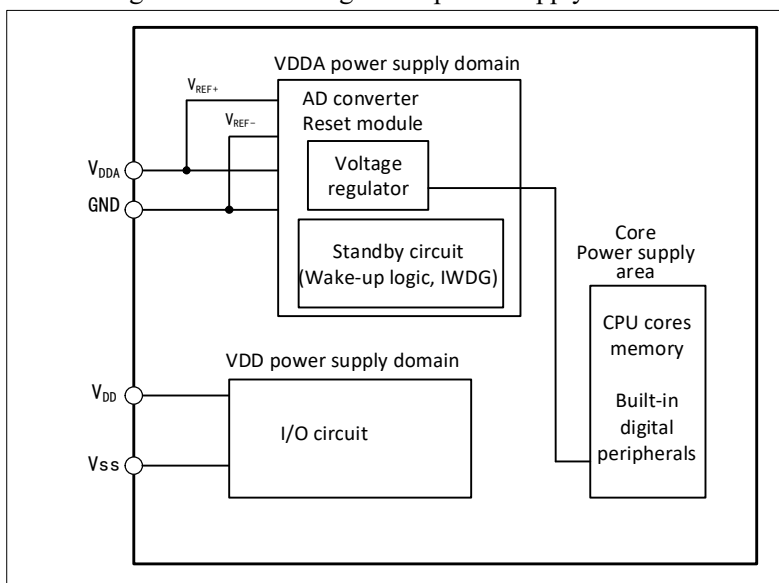

## Chapter 2 Power Control (PWR)

### 2.1 Overview

The system operating voltage  $V_{DD}$  ranges from 2 to 5.5V and the built-in voltage regulator provides the low voltage power required by the core.

The  $V_{DD}$  and GND pins are dedicated to powering the analogue related circuits in the system, including the ADC etc.  $V_{REF+}$  and  $V_{REF-}$  are used as reference points for some analogue circuits and are equal to  $V_{DD}$  and GND inside the chip. In practice  $V_{DDA}$  and GND must be connected to the  $V_{DD}$  and  $V_{SS}$  terminals.

Figure 2-1 Block diagram of power supply structure

### 2.2 Power Management

#### 2.2.1 Power-on Reset and Power-down Reset

The system integrated a power-on reset POR and a power-down reset PDR circuit. When the chip supply voltage  $V_{DD}$  falls below the corresponding threshold voltage, the system is reset by the relevant circuit, and no additional external reset circuit is required. Please refer to the corresponding datasheet for the parameters of the power-on threshold voltage  $V_{POR}$  and the power-down threshold voltage  $V_{PDR}$ .

Figure 2-2 Schematic diagram of the operation of POR and PDR

### 2.2.2 Programmable Voltage Detector

The programmable voltage detector, PVD, is mainly used to monitor the change of the main power supply of the system and compare it with the threshold voltage set by PLS[1:0] of the power control register PWR\_CTLR, and with the external interrupt register (EXTI) setting, it can generate relevant interrupts to notify the system in time for pre-power down operations such as data saving.

The specific configuration is as follows.

- 1) Set the PLS[1:0] field of the PWR\_CTLR register and select the voltage threshold to be monitored.
- 2) Optional interrupt handling. the PVD function is internally connected to the rising/falling edge trigger setting of line 26 of the EXTI module, turning on this interrupt (Configuring EXTI) will generate a PVD interrupt when VDD drops below the PVD threshold or rises above the PVD threshold.
- 3) Read the PVD0 bit of the PWR\_CSR status register can obtain the current system mains power in relation to the PLS[1:0] setting threshold and perform the corresponding soft processing. When the VDD voltage is higher than the threshold set by PLS[1:0], PVD0 position 0; when the VDD voltage is lower than the threshold set by PLS[1:0], PVD0 position 1.

Figure 2-3 Schematic diagram of PVD operation

## 2.3 Low-power Modes

After a system reset, the microcontroller is in a normal operating state (Run mode), where system power can be saved by reducing the system main frequency or turning off the unused peripheral clock or reducing the operating peripheral clock. If the system does not need to work, you can set the system to enter low-power mode and let the system jump out of this state by specific events.

Microcontrollers currently offer 3 low-power modes, divided in terms of operating differences between processors, peripherals, voltage regulators, etc.

- Sleep mode: The core stops running and all peripherals (Including core private peripherals) are still running.
- Stop mode: Stops all clocks and the system continues to run after waking up.
- Standby mode: Stops all clocks and the system continues to run after waking up.

Table 2-1 Low-power mode list

| Mode    | Entry                                               | Wake-up source                                                                                      | Effect on clock                           | Voltage regulator |
|---------|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------|-------------------------------------------|-------------------|
| Sleep   | WFI                                                 | Any interrupt                                                                                       | Core clock OFF, no effect on other clocks | Standard mode     |
|         | WFE                                                 | Wake-up event                                                                                       |                                           |                   |
| Stop    | Set SLEEPDEEP to 1<br>Clear PDDS to 0<br>WFI or WFE | Any external interrupt/event (EXTI signal), external reset signal on RST, IWDG reset <sup>(1)</sup> | Disable HIS, peripheral clock             | Standard mode     |
| Standby | Set SLEEPDEEP to 1<br>Set PDDS to 1<br>WFI or WFE   | Any external interrupt/event (EXTI signal), external reset signal on RST, IWDG reset <sup>(1)</sup> | Disable HIS, peripheral clock             | Low-power mode    |

Note: The SLEEPDEEP bit belongs to the core private peripheral control bit, reference PFIC\_SCTLR register.

(1) Using the IWDG reset function, HSI must not be turned off.

### 2.3.1 Low-power Configuration Options

- WFI and WFE

WFI: The microcontroller is woken up by an interrupt source with interrupt controller response, and the interrupt

service function will be executed first after the system wakes up (Except for microcontroller reset).

WFE: The wakeup event triggers the microcontroller to exit low-power mode. Wake-up events include:

- 1) Configure an external or internal EXTI line to event mode, when no interrupt controller needs to be configured.
- 2) Or configure an interrupt source, equivalent to a WFI wakeup, where the system prioritizes the execution of the interrupt service function.
- 3) Or configure the SEVONPEND bit to turn on peripheral interrupt enable, but not interrupt enable in the interrupt controller, and the interrupt pending bit needs to be cleared after the system wakes up.

- **SLEEPONEXIT**

Enable: After executing the WFI or WFE instruction, the microcontroller ensures that all pending interrupt services are exited and then enters low-power mode.

Disable: The microcontroller enters low-power mode immediately after executing the WFI or WFE command.

- **SEVONPEND**

Enable: All interrupts or wake-up events can wake up the low-power consumption entered by executing WFE.

Disable: Only interrupts or wake-up events enabled in the interrupt controller can wake up the low-power consumption entered by executing WFE.

### 2.3.2 Sleep Mode

In this mode, all IO pins keep their state in Run mode and all peripheral clocks are normal, so try to turn off useless peripheral clocks before entering Sleep mode to reduce low-power consumption. This mode takes the shortest time to wake up.

Enter: Configure core register control bit SLEEPDEEP=0, power control register PDDS=0, execute WFI or WFE, optionally SEVONPEND and SLEEPONEXIT.

Exit: Arbitrary interrupt or wakeup event.

### 2.3.3 Stop Mode

Stop mode is a combination of peripheral clock control mechanisms based on the core's deep sleep mode (SLEEPDEEP) and allows the voltage regulator to operate in a much lower power consumption state. In this mode the high frequency clock (HSI) domain is switched off, the SRAM and register contents are maintained and the IO pin state is held. The system can continue to run after this mode wakes up and the HSI is called the default system clock.

If flash programming is in progress, the system does not enter stop mode until access to memory is complete. Modules that can work in stop mode: Independent Watchdog (IWDG).

Enter: Configure the core register control bit SLEEPDEEP=1, PDDS=0 in the power control register, execute WFI or WFE, optionally SEVONPEND and SLEEPONEXIT.

Exits:

- 1) Any external interrupt/event (Set in the external interrupt register).
- 2) External reset, IWDG reset on RST pin.

### 2.3.4 Standby Mode

Standby mode can work modules: Independent Watchdog (IWDG).

Enter: Configure the core register control bit SLEEPDEEP=1, PDDS=1 in the power control register, and execute WFI or WFE, optionally SEVONPEND and SLEEPONEXIT.

Exit:

- 1) Any external interrupt/event (Set in the external interrupt register).
- 2) External reset, IWDG reset on RST pin.

### 2.3.5 Auto-wakeup (AWU)

The AWU module enables automatic wake-up without external interrupts. Wake-up from stop or standby mode can be done periodically by programming the time base.

The 47KHz divided clock of the internal high-speed clock HSI is selected as the AWU module clock source.

The AWU module is capable of waking up the MCU from shutdown mode, in order to realize this function, the external interrupt line 27 needs to be configured.

## 2.4 Register Description

Table 2-2 PWR-related registers list

| Name         | Access address | Description                   | Reset value |
|--------------|----------------|-------------------------------|-------------|
| R32_PWR_CTLR | 0x40007000     | Power control register        | 0x00000400  |
| R32_PWR_CSR  | 0x40007004     | Power control/status register | 0x00000000  |

## Chapter 3 Reset and Clock Control (RCC)

The controller provides different forms of resets and configurable clock tree structures based on the division of power areas and peripheral power management considerations in the application. This section describes the scope of each clock in the system.

### 3.1 Main Features

- Multiple reset forms
- Multiple clock sources, bus clock management
- Independent management of each peripheral clock: Reset, On, Off
- Supports internal clock output

### 3.2 Reset

The controller provides 2 forms of reset: Power Reset and System Reset.

#### 3.2.1 Power Reset

When a power reset occurs, all registers are reset and the PC pointer in the application is fixed at address 0x00000004 (Reset vector table).

A power Reset is generated when the following event occurs:

- Power-up/power-down reset (POR/PDR)

#### 3.2.2 System Reset

When a system Reset occurs, it will reset the reset flag in addition to the control/status register `RCC_RSTSCKR` and all the registers. The source of the reset event is identified by looking at the reset status flag bit in the `RCC_RSTSCKR` register.

A system Reset is generated when one of the following events occurs:

- Low signal on NRST pin (External reset)
- Window watchdog count termination (WWDG reset)
- Independent watchdog count termination (IWDG reset)
- Software reset (SW reset)
- Low-power management reset
- Core deadlock reset
- OPA reset
- USB PD reset
- ADC reset

Window/Independent Watchdog Reset: Generated by the window/independent watchdog peripheral timer count cycle overflow trigger, see its corresponding section for detailed description.

Software reset: Resets the system by resetting the interrupt configuration register `PFIC_CFGR` to `SYSRST` position 1 in the programmable interrupt controller PFIC or configuration register `PFIC_SCTLR` to `SYSRST` position 1, refer to the corresponding chapter. Low Power Management Reset: A standby mode reset will be enabled by setting `STANDY_RST` position 0 in the user option byte. At this point after performing the process of entering standby mode, a system reset will be performed instead of entering standby mode. A shutdown mode reset will be enabled

by setting STOP\_RST to position 0 in the user option byte. This will perform a system reset instead of entering shutdown mode after the process of entering shutdown mode has been executed.

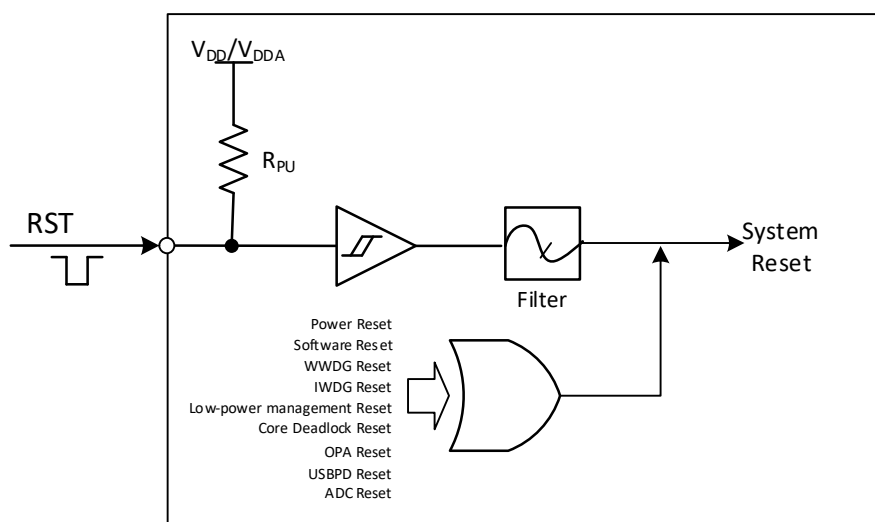

Core Deadlock Reset: With System Control Register [6] at 0, a deadlock reset will be generated when the core addresses an exception or enters an NMI interrupt, Note: A deadlock reset cannot be generated in the modulation mode.

OPA reset: When OPA reset enable is on, an OPA reset will be generated when the op-amp output goes high.

USB PD reset: When PD\_RST\_EN is 1, CH643 supports the reset generated by USB PD signal frame Hard Reset; if IE\_RX\_RESET is also 1, it also supports the reset generated by signal frame Cable Reset. The USB PD does not have a reset flag, but produces the same reset effect as a software reset.

ADC Reset: If the ADC watchdog reset enable is on, an ADC reset is generated when the ADC data is greater than the watchdog high threshold or less than the watchdog low threshold.

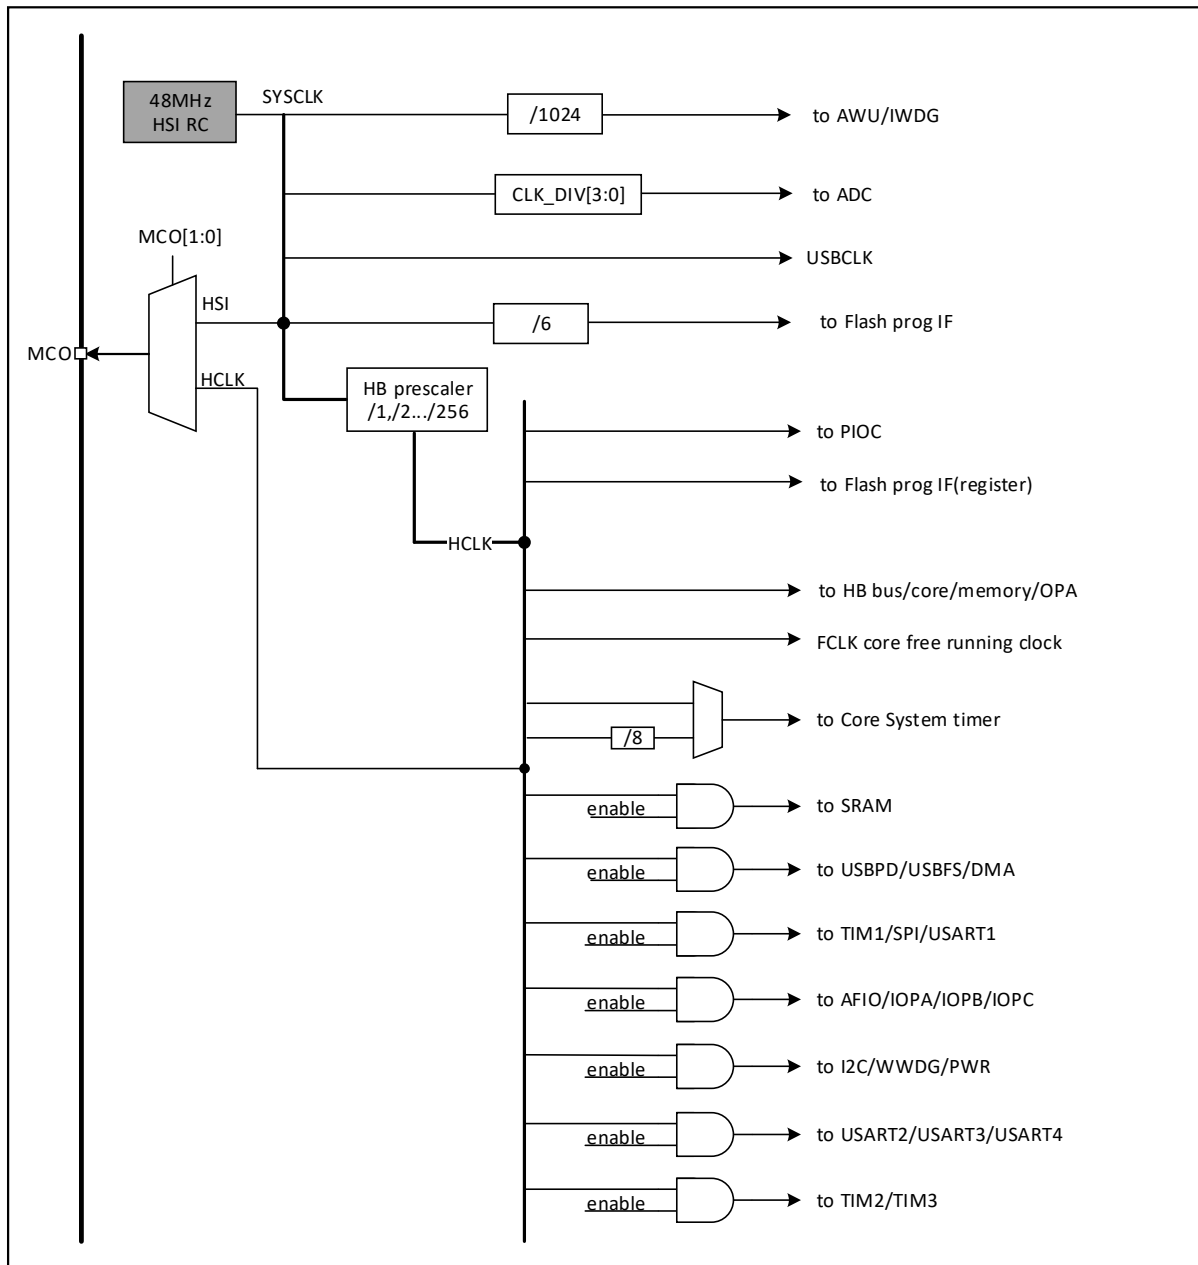

Figure 3-1 System reset structure

### 3.3 Clock

#### 3.3.1 System Clock Structure

Figure 3-2 CH643 clock tree block diagram

### 3.3.2 High-speed Clock (HSI)

HSI is a high-speed clock signal generated by the system internal 48MHz RC oscillator. HSI RC oscillator can provide system clock without any external devices. It has a short start-up time. HSI is enabled and disabled by setting the HSION bit in the RCC\_CTLR register, and the HSIRDY bit indicates whether the HSI RC oscillator is stable or not. The system defaults HSION and HSIRDY to 1 (It is recommended not to turn them off).

- Factory calibration: The difference of manufacturing process will cause different RC oscillation frequency for each chip, so HSI calibration is performed for each chip before it is shipped. After system reset, the factory calibration value is loaded into HSICAL[7:0] of the RCC\_CTLR register.
- User tuning: Based on different voltages or ambient temperatures, the application can adjust the HSI frequency by using the HSITRIM[4:0] bits in the RCC\_CTLR register.

### 3.3.3 Bus/Peripheral Clock

#### 3.3.3.1 System Clock (SYSCLK)

The default HSI clock is the system clock source.

#### 3.3.3.2 HB Bus Peripheral Clock (HCLK)

The HB bus clocks can be configured by configuring the HPRE[3:0] bits of the RCC\_CFGR0 register. The bus clock determines the peripheral interface access clock reference that is mounted below them. Applications can adjust different values to reduce the power consumption when some of the peripherals are operating.

The various bits in the RCC\_AHBSTR, RCC\_APB1PRSTR and RCC\_APB2PRSTR registers can reset the different peripheral modules to their initial state.

Each bit in the RCC\_AHBPCENR, RCC\_APB1PCENR, and RCC\_APB2PCENR registers can be used to individually turn on or off the communication clock interface for different peripheral modules. When using a peripheral, you first need to turn on its clock enable bit in order to access its registers.

#### 3.3.3.3 Independent Watchdog Clock

If the independent watchdog has been set by hardware configuration or started by software, the HSI oscillator will be forced on and cannot be turned off. After the HSI oscillator is stabilized, the clock is supplied to the IWDG.

#### 3.3.3.4 Microcontroller Clock Output (MCO)

The microcontroller allows outputting clock signals to the MCO pins. The following 2 clock signals can be selected as MCO clock outputs by configuring the alternate push-pull output mode in the corresponding GPIO port registers by configuring the MCO[2:0] bits of the RCC\_CFGR0 register.

- System clock (SYSCLK) output
- HSI clock output

## 3.4 Register Description

Table 3-1 RCC-related registers list

| Name              | Access address | Description                   | Reset value |
|-------------------|----------------|-------------------------------|-------------|
| R32_RCC_CTLR      | 0x40021000     | Clock control register        | 0x0000xx83  |
| R32_RCC_CFGR0     | 0x40021004     | Clock configuration register  | 0x00000000  |
| R32_RCC_APB2PRSTR | 0x4002100C     | PB2 peripheral reset register | 0x00000000  |

|                   |            |                                      |            |
|-------------------|------------|--------------------------------------|------------|
| R32_RCC_APB1PRSTR | 0x40021010 | PB1 peripheral reset register        | 0x00000000 |
| R32_RCC_AHBPCENR  | 0x40021014 | HB peripheral clock enable register  | 0x00000014 |
| R32_RCC_APB2PCENR | 0x40021018 | PB2 peripheral clock enable register | 0x00000000 |
| R32_RCC_APB1PCENR | 0x4002101C | PB1 peripheral clock enable register | 0x00000000 |
| R32_RCC_RSTSCKR   | 0x40021024 | Control/status register              | 0x0C000000 |
| R32_RCC_AHBSTR    | 0x40021028 | HB peripheral reset register         | 0x00000000 |

## Chapter 4 Auto-wakeup (AWU)

The AWU module enables automatic wake-up without external interrupts. Wake-up from stop or standby mode can be done periodically by programming the time base.

### 4.1 Main Features

- 6-bit self-adding counter
- Select the 47KHz divided clock of the internal high-speed clock HSI as the AWU module clock source, which can be operated in low-power mode
- Wake-up condition: when the counter counts to a value equal to the one written in

### 4.2 Function Description

The AWU module is capable of waking up the MCU from low-power mode, and in order to realize this function, the external interrupt line 27 needs to be configured.

### 4.3 Register Description

Table 4-1 AWU-related registers list

| Name        | Access address | Description             | Reset value |

## Chapter 5 Independent Watchdog (IWDG)

The system has an independent watchdog (IWDG) to detect logic errors and software faults caused by external environmental disturbances. the IWDG clock is sourced from a 1024 division of the internal high-speed clock HSI (47KHz) and can be run independently of the main program for applications requiring low accuracy.

### 5.1 Main Features

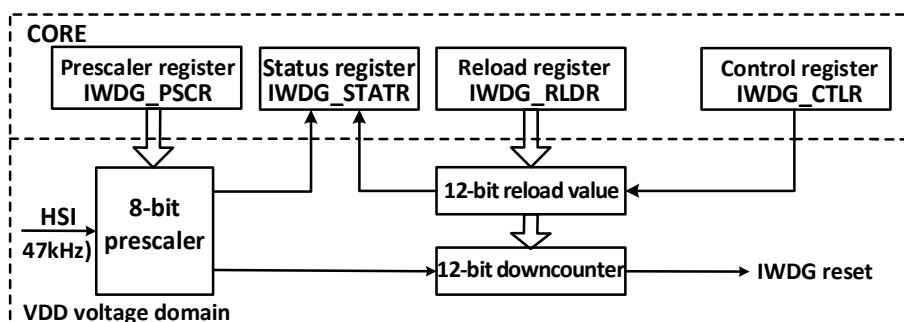

- 12-bit self-subtracting counter
- Clock source HSI divided by 1024 (47KHz), can run in low-power mode
- Reset condition: Counter value is reduced to 0

### 5.2 Function Description

#### 5.2.1 Principle and Application

The independent watchdog is clocked from the HSI clock and its function remains functional during shutdown and Standby modes. When the watchdog counter self-decreases to 0, a system Reset will be generated, so the timeout is (Reload value + 1) clock.

Figure 5-1 Block diagram of the structure of the independent watchdog

- Enable independent watchdog

After a system reset, the watchdog is off and writing 0xCCCC to the IWDG\_CTLR register turns the watchdog on, after which it cannot be turned off again unless a reset occurs.

If the hardware independent watchdog enable bit (IWDG\_SW) is turned on at the user option byte, IWDG will be fixed on after a microcontroller reset.

- Watchdog configuration

The watchdog is internally a 12-bit counter that runs decreasingly. When the counter value decreases to 0, a system Reset will occur. To turn on the IWDG function, the following actions need to be performed.

- 1) Counting time base: IWDG clock source HSI divided by 1024, set the HSI crossover value clock as the counting time base of IWDG through the IWDG\_PSCR register. The operation method first writes 0x5555 to the IWDG\_CTLR register, and then modifies the crossover value in the IWDG\_PSCR register. the PVU bit in the IWDG\_STATR register indicates the update status of the crossover value, and the crossover value can be modified and read out only when the update is completed.
- 2) Reload value: Used to update the current value of the counter in the standalone watchdog and the counter is

decremented by this value. The RVU bit in the IWDG\_STATR register indicates the update status of the reload value, and the IWDG\_RLDR register can be modified and read out only when the update is completed.

- 3) Watchdog enable: write 0xCCCC to the IWDG\_CTLR register to enable the watchdog function.
- 4) Feed the dog: i.e., flush the current counter value before the watchdog counter decrements to 0 to prevent a system reset from occurring. Write 0xAAAA to the IWDG\_CTLR register to allow the hardware to update the IWDG\_RLDR register value to the watchdog counter. This action needs to be executed regularly after the watchdog function is turned on, otherwise a watchdog reset action will occur.

## 5.2.2 Debug Mode

When the system enters Debug mode, the counter of IWDG can be configured by the debug module register to continue or stop.

## 5.3 Register Description

Table 5-1 IWDG-related registers list

| Name           | Access address | Description        | Reset value |
|----------------|----------------|--------------------|-------------|

*Note: After the prescaler or reload value is updated, it is not necessary to wait for the RVU or PVU to reset, and the following code can continue to be executed. (This write operation will continue to be executed to completion even in low-power mode.)*

● Watchdog Configuration

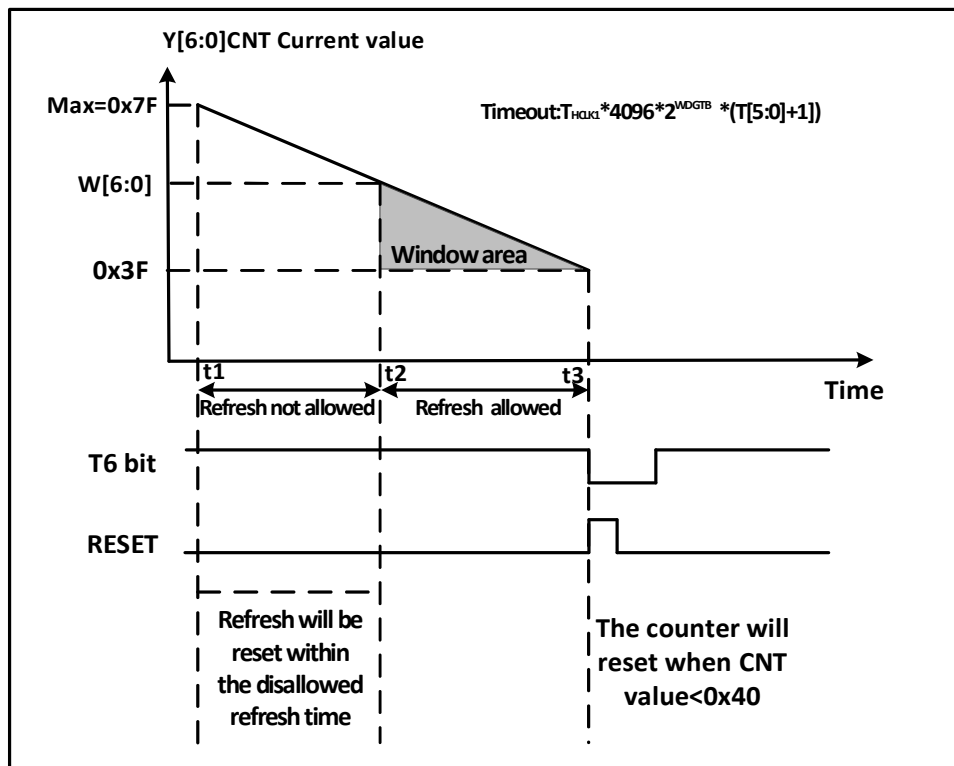

The watchdog is internally a 7-bit counter that runs in a continuous decreasing cycle and supports read and write access. To use the watchdog reset function, the following actions need to be performed.

- 1) Counting time base: via the WDGTB[1:0] bit field of the WWDG\_CFGR register, note that the WWDG module clock of the RCC unit should be turned on.
- 2) Window counter: Set the W[6:0] bit field of WWDG\_CFGR register, this counter is used by hardware as a comparison with the current counter, the value is configured by user software and will not change. It is used as the upper limit value of the window time.
- 3) Watchdog enable: WDG\_CTLR register WDGA bit software set to 1, to turn on the watchdog function, you can system reset.
- 4) Feed the dog: i.e., refresh the current counter value and configure the T[6:0] bit field of the WWDG\_CTLR register. This action needs to be executed within the periodic window time after the watchdog function is turned on, otherwise a watchdog reset action will occur.

● Dog feeding window time

As shown in Figure 6-2, the gray area is the monitoring window area of the window watchdog, whose upper time t2 corresponds to the point in time when the current counter value reaches the window value W[6:0]; its lower time t3 corresponds to the point in time when the current counter value reaches 0x3F. This area time t2<t<t3 can be fed with a dog operation (Write T[6:0]) to refresh the current counter value.

Figure 6-2 Counting mode of Window Watchdog

● Watchdog reset

- 1) When the value of T[6:0] counter changes from 0x40 to 0x3F due to no timely dog feeding operation, a "window watchdog reset" will occur and a system reset will be generated. That is, the T6-bit is detected as 0 by the hardware and a system reset will occur.

*Note: The application can write T6-bit to 0 by software to achieve system Reset, which is equivalent to software reset function.*

- 2) When the counter refresh action is executed within the disallowed dog feeding time, i.e., the write T[6:0] bit field is operated within  $t_1 \leq t \leq t_2$  time, a "window watchdog reset" will occur and a system Reset will be generated.

- Wake up in advance

To prevent the system Reset caused by not refreshing the counter in time, the watchdog module provides an early wakeup interrupt (EWI) notification. When the counter self-decreases to 0x40, an early wake-up signal is generated and the EWIF flag is set to 1. If the EWI bit is set, a window watchdog interrupt will be triggered at the same time. At this time, there is 1 counter clock cycle (Self-decrement to 0x3F) before the hardware reset, and the application can perform the dog feeding operation instantly within this time.

### 6.2.2 Debug Mode

When the system enters Debug mode, the counter of WWDG can be configured by the debug module register to continue or stop.

## 6.3 Register Description

Table 6-1 WWDG-related registers list

| Name           | Access address | Description            | Reset value |
|----------------|----------------|------------------------|-------------|
| R16_WWDG_CTLR  | 0x40002C00     | Control register       | 0x007F      |
| R16_WWDG_CFGR  | 0x40002C04     | Configuration Register | 0x007F      |
| R16_WWDG_STATR | 0x40002C08     | Status Register        | 0x0000      |

### 6.3.1 Control Register (WWDG\_CTLR)

Offset address: 0x00

| 0      | EWIF     | RW0    | Wake up the interrupt flag bit early.<br>When the counter reaches 0x40, this bit is set in hardware and must be cleared to 0 by software; the user setting is invalid. Even if the EWI is not set, this bit will still be set as usual when the event occurs. | 0           |

## Chapter 7 Interrupt and Events (PFIC)

CH643 has a built-in Programmable Fast Interrupt Controller (PFIC) that supports up to 255 interrupt vectors. The current system manages 39 peripheral interrupt channels and 7 core interrupt channels, the others are reserved.

### 7.1 Main Features

#### 7.1.1 PFIC

- 39 peripheral interrupts, each interrupt request has independent trigger and mask control bits, with dedicated status bits
- Programmable multi-level interrupt nesting, maximum nesting depth 2 levels, hardware stack depth 2 levels
- Fast interrupt entry and exit mechanism, hardware automatic stacking and recovery
- Vector Table Free (VTF) interrupt response mechanism, 4-channel programmable direct access to interrupt vector addresses

### 7.2 System Timer

- CH643 Series

The core comes with a 64-bit add counter (SysTick) that supports HCLK or HCLK/8 as a time base with high priority and can be used as a time reference after calibration.

### 7.3 Vector Table of Interrupts and Exceptions

Table 7-1 CH643 series vector table

| No.   | Priority | Type         | Name       | Description                        | Entrance address          |

## 7.4 External Interrupt and Event Controller (EXTI)

### 7.4.1 Overview

Figure 7-1 External interrupt (EXTI) interface block diagram

As can be seen from Figure 7-1, the trigger source of the external interrupt can be either a software interrupt (SWIEVR) or an actual external interrupt channel. The signal of the external interrupt channel will be screened by the edge detect circuit first. Whenever one of the software interrupt or external interrupt signals is generated, it will be output to two with-gate circuits, event enable and interrupt enable, through the or-gate circuit in the figure, as long as an interrupt is enabled or an event is enabled, an interrupt or an event will be generated. six registers of EXTI are accessed by the processor through the HB interface.

### 7.4.2 Wake-up Event

The system can wake up the Sleep mode caused by the WFE command through a wake-up event. The wake-up event is generated by either of the following two configurations.

- Enable an interrupt in a peripheral register, but not enabling this interrupt in the PFIC of the core, and enabling the SEVONPEND bit in the core at the same time. Embodied in EXTI, it is to enable an EXTI interrupt, but not to enable the EXTI interrupt in PFIC, and to enable the SEVONPEND bit at the same time. When the CPU wakes up from WFE, it needs to clear the EXTI interrupt flag bit and the PFIC pending bit.
- Enable an EXTI channel as an event channel eliminates the need for the CPU to clear the interrupt flag bit and the PFIC pending bit after waking up from the WFE.

### 7.4.3 Description

Using an external interrupt requires configuring the corresponding external interrupt channel, i.e. selecting the corresponding trigger edge and enabling the corresponding interrupt. When the set trigger edge appears on the external interrupt channel, an interrupt request will be generated and the corresponding interrupt flag bit will be set. The flag bit can be cleared by writing 1 to the flag bit.

Steps for using external hardware interrupts.

- 1) Configuration of GPIO operations.
- 2) Configure the interrupt enable bit (EXTI\_INTENR) for the corresponding external interrupt channel.
- 3) Configuring the trigger edge (EXTI\_RTENR or EXTI\_FTENR) to select rising edge trigger, falling edge trigger or double edge trigger.
- 4) Configure EXTI interrupts in the core's PFIC to ensure they can respond correctly.

Steps for using external hardware events.

- 1) Configuration of GPIO operations.
- 2) Configure the event enable bit (EXTI\_EVENTR) for the corresponding external interrupt channel.
- 3) Configure the trigger edge (EXTI\_RTENR or EXTI\_FTENR) to select rising edge trigger, falling edge trigger, or double edge trigger.

Using the software interrupt/event steps.

- 1) Enabling external interrupts (EXTI\_INTENR) or external events (EXTI\_EVENTR).
- 2) If using interrupt service functions, the EXTI interrupt needs to be set in the core's PFIC.
- 3) Set the software interrupt trigger (EXTI\_SWIEVR), that is, an interrupt will be generated.

### 7.4.4 External Event Mapping

Table 7-2 EXTI interrupt mapping

| External interrupt/<br>Event lines | Mapping event description                                                                                                                |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| EXTI0-EXTI23                       | Px0-Px23 (x=A/B/C), any of the I/O ports can be enabled for external interrupt/event functions, configured by the AFIO_EXTICRx register. |
| EXTI24                             | Enabled on the 2-wire debug interface for PC18 to enable external interrupts or event wake-up                                            |
| EXTI25                             | Enabled on the 2-wire debug interface for PC19 to enable external interrupts or event wake-up                                            |
| EXTI26                             | PVD event: voltage monitoring threshold exceeded                                                                                         |
| EXTI27                             | AWU auto-wakeup event                                                                                                                    |
| EXTI28                             | USB wakeup event                                                                                                                         |
| EXTI29                             | USB PD wakeup event                                                                                                                      |

## 7.5 Register Description

### 7.5.1 EXTI Registers

Table 7-3 EXTI-related registers list

| Name            | Access address | Description                          | Reset value |
|-----------------|----------------|--------------------------------------|-------------|
| R32_EXTI_INTENR | 0x40010400     | Interrupt enable register            | 0x00000000  |
| R32_EXTI_EVENTR | 0x40010404     | Event enable register                | 0x00000000  |
| R32_EXTI_RTENR  | 0x40010408     | Rising edge trigger enable register  | 0x00000000  |
| R32_EXTI_FTENR  | 0x4001040C     | Falling edge trigger enable register | 0x00000000  |
| R32_EXTI_SWIEVR | 0x40010410     | Soft interrupt event register        | 0x00000000  |
| R32_EXTI_INTFR  | 0x40010414     | Interrupt flag register              | 0x0000XXXX  |

| [31:30] | Reserved | RO | Reserved                                                                                                                                                                                                                                                                                                       | 0 |
| [29:0]  | SWIERx   | RW | A software interrupt is set on the corresponding externally triggered interrupt channel. Setting it here causes the interrupt flag bit (EXTI_INTFR) to correspond to the position bit, and if interrupt enable (EXTI_INTENR) or event enable (EXTI_EVENR) is on, then an interrupt or event will be generated. | 0 |

| R32_PFIC_IACTR4  | 0xE000E30C | PFIC interrupt activation status register 4    | 0x00000000 |
| R32_PFIC_IPRIORx | 0xE000E400 | PFIC interrupt priority configuration register | 0x00000000 |
| R32_PFIC_SCTLR   | 0xE000ED10 | PFIC system control register                   | 0x00000000 |

Note: 1. NMI, EXC, ECALL-M, ECALL-U and BREAKPOINT interrupts are always enabled by default.

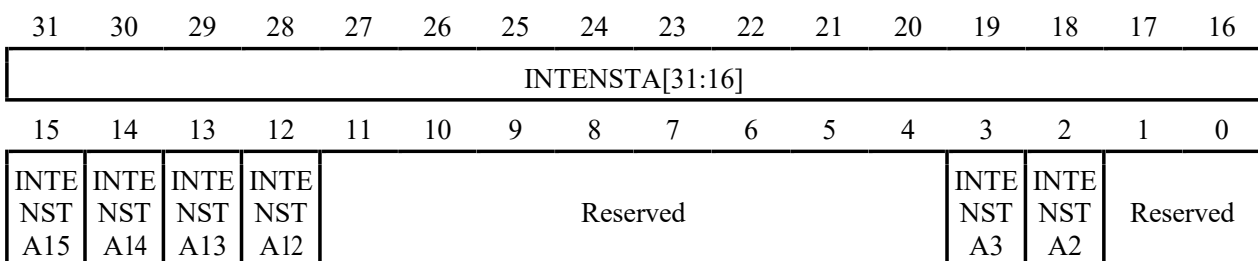

2. ECALL-M, ECALL-U and BREAKPOINT are all cases of EXC and their status is indicated by bit 3 of the EXC status bit.

3. NMI and EXC support interrupt pending clear and set operations, but do not support interrupt enable clear and set operations.

4. ECALL-M, ECALL-U and BREAKPOINT do not support interrupt pending clear and set, interrupt enable clear and set operations.

### 7.5.2.1 PFIC Interrupt Enable Status Register 1 (PFIC\_ISR1)

Offset address: 0x00

### 7.5.2.37 PFIC Interrupt Priority Configuration Register (PFIC\_IPRIORx) (x=0-63)

Offset address: 0x400-0x4FF

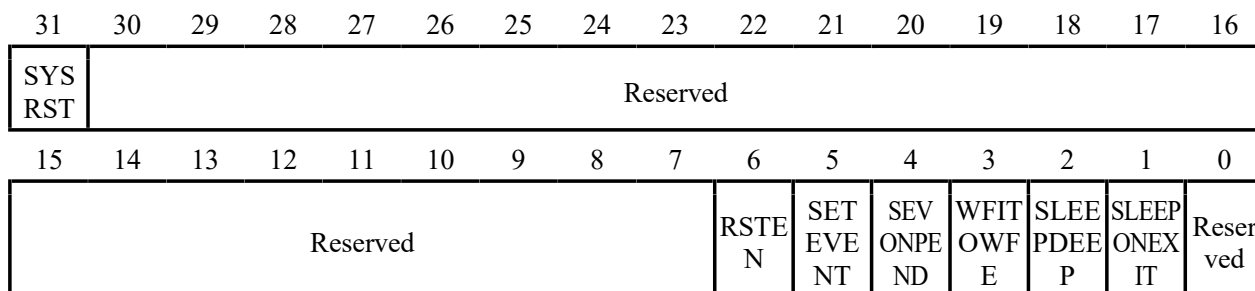

The controller supports 256 interrupts (0-255), each using 8 bits to set the control priority.

| Bit         | Name   | Access | Description                                                                                                                                                                                                                                                                                                                                                                                                                                       | Reset value |

### 7.5.3 Dedicated CSR Registers

A number of Control and Status Registers (CSRs) are defined in the RISC-V architecture to configure or identify or record operational status. In addition to the standard registers defined in the RISC-V Privileged Architecture document, the CH643 chip also has a number of vendor-defined registers that need to be accessed using the csr instruction.

*Note: These registers are labeled "MRW, MRO, MRW1" and require the system to be in machine mode to access them.*

#### 7.5.3.1 Interrupt System Control Register (INTSYSCR)

CSR address: 0x804

## 7.5.4 Physical Memory Protection Unit (PMP)

To improve system security, a set of physical address access restrictions are defined in RISC-V's architecture, which can set their read, write and execute attributes for the physical memory in the region, with a minimum region length of 4 bytes protected. the PMP unit is always in effect in user mode, and optionally in machine mode, and will generate a system exception interrupt (EXC) if the current memory restrictions are violated.

The PMP cell contains 4 sets of 8-bit configuration registers (32bit) and 4 sets of address registers which need to be accessed using the csr instruction and are in machine mode.

### 7.5.4.1 PMP Configuration Register (PMPCFG0)

|         |         |        | 1            | W    | Writable attributes.                                                                            |             |
|         |         |        | 0            | R    | Readable attributes.                                                                            |             |

Among them, address alignment and protection region range selection, for  $A\_ADDR \leq \text{region} < B\_ADDR$  region for memory protection (Requiring both  $A\_ADDR$  and  $B\_ADDR$  to be 4-byte aligned):

1. If  $B\_ADDR - A\_ADDR = 2^2$ , the NA4 method is used;
2. If  $B\_ADDR - A\_ADDR = 2^{(G+2)}$ ,  $G \geq 1$  and  $A\_ADDR$  is  $2^{(G+2)}$  aligned then the NAPOT method is used;
3. Otherwise the TOR method is used.

| A value | Name | Description                                                                                                                                                                                                                                     |

### 7.5.5.2 System Count Status Register (STK\_SR)

Offset address: 0x04

| Bit    | Name     | Access | Description                                                                                                                                                               | Reset value |
|--------|----------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [31:1] | Reserved | RO     | Reserved                                                                                                                                                                  | 0           |
| 0      | CNTIF    | RW0    | Count value comparison flag, write 0 to clear, write 1 to invalidate.<br>1: Counting up to the comparison value and down to 0;<br>0: The comparison value is not reached. | 0           |

### 7.5.5.3 System Counter Low Register (STK\_CNTL)

Offset address: 0x08

| Bit    | Name      | Access | Description                                       | Reset value |
|--------|-----------|--------|---------------------------------------------------|-------------|
| [31:0] | CNT[31:0] | RW     | The current counter count value is 32 bits lower. | 0           |

Note: Register STK\_CNTL and register STK\_CNTH together form the 64-bit system counter.

### 7.5.5.4 System Counter High Register (STK\_CNTH)

Offset address: 0x0C

| Bit    | Name       | Access | Description                                        | Reset value |
|--------|------------|--------|----------------------------------------------------|-------------|
| [31:0] | CNT[63:32] | RW     | The current counter count value is 32 bits higher. | 0           |

Note: Register STK\_CNTH and register STK\_CNTH together form the 64-bit system counter.

### 7.5.5.5 Counting Comparison Low Register (STK\_CMPLR)

Offset address: 0x10

| Bit    | Name      | Access | Description                                      | Reset value |
|--------|-----------|--------|--------------------------------------------------|-------------|
| [31:0] | CMP[31:0] | RW     | Sets the comparison counter value 32 bits lower. | 0           |

Note: Register STK\_CMPLR and register STK\_CMPHR together form the 64-bit counter comparison value.

### 7.5.5.6 Counting Comparison High Register (STK\_CMPHR)

Offset address: 0x14

| Bit    | Name       | Access | Description                                       | Reset value |
|--------|------------|--------|---------------------------------------------------|-------------|
| [31:0] | CMP[63:32] | RW     | Sets the comparison counter value 32 bits higher. | 0           |

Note: Register STK\_CMPLR and register STK\_CMPHR together form the 64-bit counter comparison value.

## Chapter 8 GPIO and Alternate Function (GPIO/AFIO)

The GPIO ports can be configured into various input or output modes, with built-in pull-up resistors that can be closed, and some GPIOs have built-in pull-down resistors that can be closed, and can be configured into push-pull functions. the GPIO ports can also be multiplexed into other functions.

PA0-PA7, PB0-PB1, PC0-PC3 and PC20 support ADC analogue signal input channels 0 to 14.

All GPIO pins support controlled pull-up, only PA0-PA15 and PC16-PC17 support controlled pull-down, the remaining pins do not support pull-down. PC14-PC17 support multiple pull-up modes, which are set by the dedicated control registers corresponding to the PD and USB pins respectively.

All PA and PB GPIOs have high current drive capability and both support PWM; all PA pins have source current simple constant current function and sink current simple constant current function; all PB pins have sink current simple constant current function and have high sink current drive capability as fully built-in COM driver.

Pins PA0-PA15 have a current mode key detection function (NKEY\_MODE) with active fill current; pins PB0-PB15 have a current mode key detection function (PKEY\_MODE) with active source current.

### 8.1 Main Features

Each pin of the port can be configured to one of the following multiple modes.

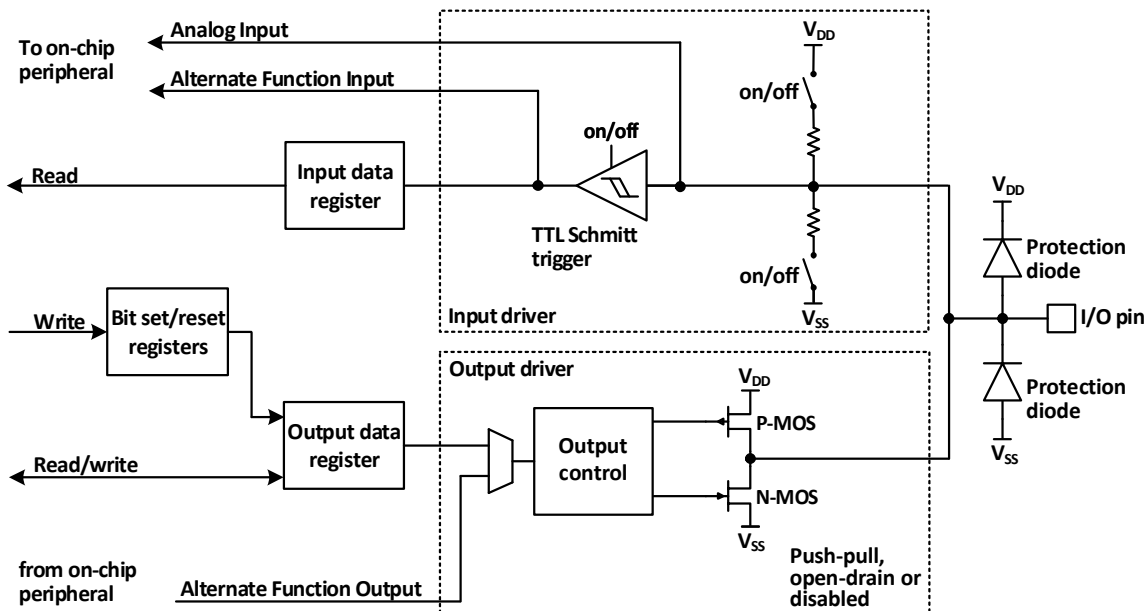

- Floating input
- Pull-up input
- Pull-down input (Partial IO)
- Analog input
- Push-pull output
- Inputs and outputs of alternate functions

Many pins have alternate capabilities, and many other peripherals map their output and input channels to these pins. The specific usage of these alternate pins needs to be referred to the individual peripherals, and the content of whether these pins are alternate and remapped is explained in this chapter.

## 8.2 Function Description

### 8.2.1 Overview

Figure 8-1 GPIO module basic structure block diagram

As shown in Figure 8-1 IO port structure, each pin has two protection diodes inside the chip, and the IO port can be internally divided into input and output driver modules. The input driver has a pull-up resistor and a pull-down resistor (Only for some of the IOs) to choose from, and can be connected to peripherals with analogue inputs such as AD; if the input is to a digital peripheral, it needs to go through a TTL Schmitt trigger and then be connected to a GPIO input register or other multiplexed peripherals. The output driver, on the other hand, has a pair of MOS tubes that can configure the IO port as a push-pull output; the output driver can also be configured internally as to whether the output is controlled by the GPIO or by another peripheral that is multiplexed.

### 8.2.2 GPIO Initialization Function

Just after a reset, the GPIO ports are running in their initial state, when most IO ports are running in the floating input state, but there are also peripheral related pins that are running on the peripheral multiplexing function. Please refer to the relevant section of the pin description for the specific initialization function.

### 8.2.3 External Interrupts

All GPIO ports can be configured with external interrupt input channels, but an external interrupt input channel can only be mapped to at most one GPIO pin, and the serial number of the external interrupt channel must be the same as the bit number of the GPIO port, for example, PA1 (Or PB1, PC1) can only be mapped to EXTI1, and EXTI1 can only accept one of PA1, PB1 or PC1. The mapping of both parties is one-to-one.

### 8.2.4 Alternate Functions

It is important to note that using the alternate function.

- To use the alternate function in the input direction, the port must be configured in alternate input mode, and the pull-down settings can be set according to actual needs.
- To use the alternate function in the output direction, the port must be configured in alternate output mode.

- For bidirectional alternate function, the port must be configured in alternate output mode, when the driver is configured in floating input mode

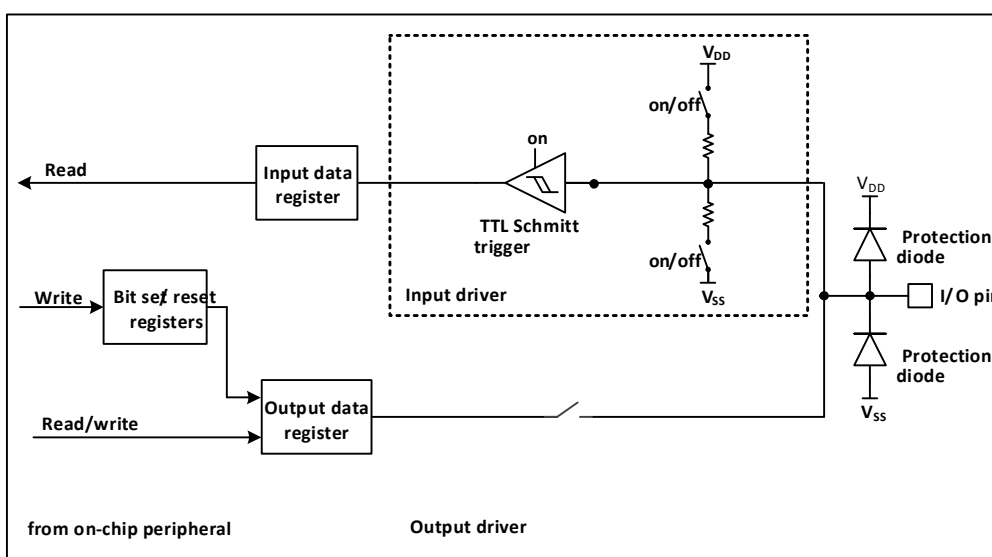

The same IO port may have multiple peripherals alternate to this pin, so in order to maximize the space for each peripheral, the alternate pins of peripherals can be remapped to other pins in addition to the default alternate pins, avoiding the occupied pins.

### 8.2.5 Locking Mechanism

The locking mechanism locks the configuration of the I/O port. After a specific write sequence, the selected I/O pin configuration will be locked and cannot be changed until the next reset.

### 8.2.6 Input Configuration

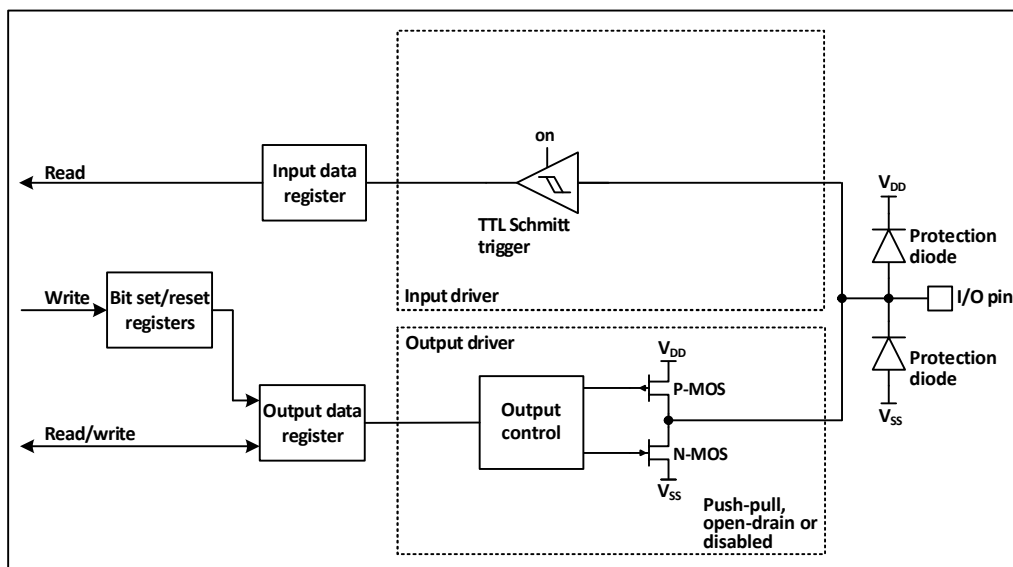

Figure 8-2 GPIO module input configuration structure block diagram

When the IO port is configured in input mode, the output driver is disconnected, the input pull-up and pull-down are selectable, and no alternate functions or analogue inputs are connected. The data on each IO port is sampled at each HB clock into the input data register and the level status of the corresponding pin is obtained by reading the corresponding bit in the input data register.

### 8.2.7 Output Configuration

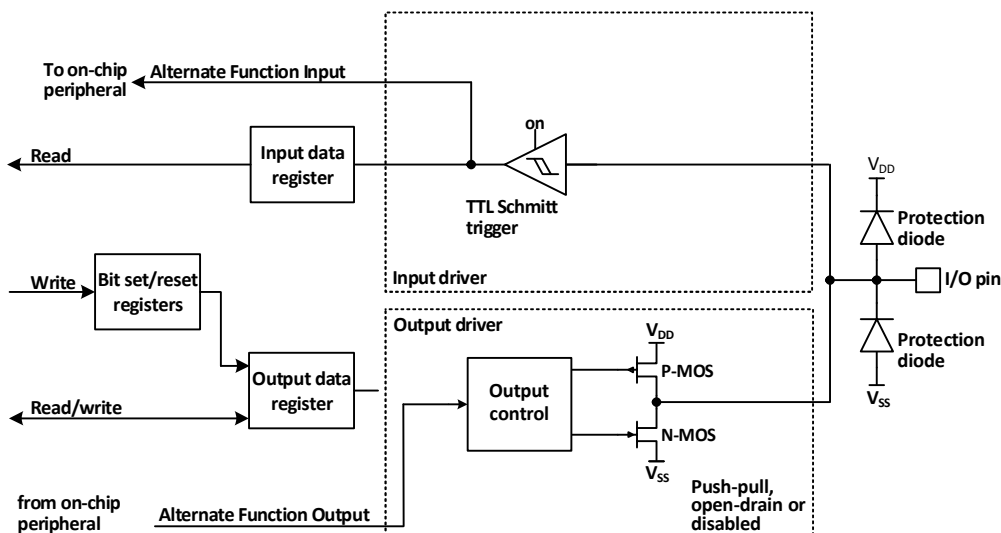

Figure 8-3 GPIO module output configuration structure block diagram

When the IO port is configured in output mode, the output driver is configured in push-pull mode and does not use the multiplexing function. The input driver's pull-up and pull-down resistors are disabled, the TTL Schmitt trigger is activated and the levels appearing on the IO pins will be sampled into the input data registers at each HB clock, so reading the input data registers will give the IO status and access to the output data registers will give the last written value.

### 8.2.8 Alternate Function Configuration

Figure 8-4 The structure of GPIO module when it is alternate by other peripherals

When alternate is enabled, the output drivers are enabled, configured in push-pull mode, or automatically configured in open-drain mode if used for I2C, the Schmitt trigger is turned on, the input and output lines of the alternate function are connected, but the output data registers are disconnected, the levels present on the IO pins will be sampled into the input data registers at each HB clock, and reading the input data registers will give the current status of the IO port; in push-pull mode, reading the output data registers will give the last written value.

### 8.2.9 Analog Input Configuration

Figure 8-5 The configuration structure when the GPIO module is used as an analog input

When the analog input is enabled, the output buffer is disconnected, the input of the Schmitt trigger in the input driver is disabled to prevent the generation of consumption on the IO port, the pull-up and pull-down resistors are disabled, and the read input data register will always be 0.

### 8.2.10 GPIO Settings for Peripherals

The following table recommends the corresponding GPIO port configuration for each peripheral pin.

Table 8-1 Advanced timer (TIM1/2)

| TIM1/2      | Configuration                    | GPIO configuration         |
|-------------|----------------------------------|----------------------------|
| TIM1/2_CHx  | Input capture channel x          | Floating input             |
|             | Output comparison channel x      | Push-pull alternate output |
| TIM1/2_CHxN | Complementary output channel x   | Push-pull alternate output |
| TIM1/2_BKIN | Brake input                      | Floating input             |
| TIM1/2_ETR  | Externally triggered clock input | Floating input             |

Table 8-2 General-purpose timer (TIM3)

| TIM3 pin | Configuration                    | GPIO configuration         |
|----------|----------------------------------|----------------------------|
| TIM3_CHx | Input capture channel x          | Floating input             |
|          | Output comparison channel x      | Push-pull alternate output |
| TIM3_ETR | Externally triggered clock input | Floating input             |

Table 8-3 Universal synchronous asynchronous serial transceiver (USART)

| USART pin | Configuration    | GPIO configuration                                 |
|-----------|------------------|----------------------------------------------------|
| USARTx_TX | Full-duplex mode | Push-pull alternate output                         |
|           | Half-duplex mode | Push-pull alternate output<br>(External plus pull) |

|            |                              |                                 |
|------------|------------------------------|---------------------------------|
| USARTx_RX  | Full-duplex mode             | Floating input or pull-up input |
|            | Half-duplex synchronous mode | Not used                        |
| USARTx_CK  | Synchronous mode             | Push-pull alternate output      |
| USARTx_RTS | Hardware flow control        | Push-pull alternate output      |
| USARTx_CTS | Hardware flow control        | Floating input or pull-up input |

Table 8-4 Serial peripheral interface (SPI) modules

| SPI pin   | Configuration                               | GPIO configuration                   |
|-----------|---------------------------------------------|--------------------------------------|
| SPIx_SCK  | Master mode                                 | Push-pull alternate output           |
|           | Slave mode                                  | Floating input                       |
| SPIx_MOSI | Full-duplex Master mode                     | Push-pull alternate output           |
|           | Full-duplex Slave mode                      | Floating input or pull-up input      |
|           | Simple bi-directional data line/Master mode | Push-pull alternate output           |
|           | Simple bi-directional data line/Slave mode  | Not used                             |
| SPIx_MISO | Full-duplex Master mode                     | Floating input or pull-up input      |
|           | Full-duplex Slave mode                      | Push-pull alternate output           |
|           | Simple bi-directional data line/Master mode | Not used                             |
|           | Simple bi-directional data line/Slave mode  | Push-pull alternate output           |
| SPIx_NSS  | Hardware master/slave mode                  | Floating, pull-up or pull-down input |
|           | Hardware master mode/NSS output enable      | Push-pull alternate output           |
|           | Software mode                               | Not used                             |

Table 8-5 Internal integrated bus (I2C) module

| I2C pin | Configuration | GPIO configuration                                   |
|---------|---------------|------------------------------------------------------|
| I2C_SCL | I2C clock     | Push-pull alternate output<br>(Automatic open-drain) |
| I2C_SDA | I2C data      | Push-pull alternate output<br>(Automatic open-drain) |

Table 8-6 USB Host device (USB FS) controller

| USB FS pin  | GPIO configuration                                                                                                   |
|-------------|----------------------------------------------------------------------------------------------------------------------|
| USBDM/USBDP | After enabling the USB module, the alternate I/O port is automatically connected to the internal USB FS transceiver. |

Table 8-7 Analog-to-digital converter (ADC)

| ADC pin | GPIO configuration |
|---------|--------------------|
| ADC     | Analog input       |

Table 8-8 OPA function settings

| Pin | Configuration function | GPIO configuration |
|-----|------------------------|--------------------|
|-----|------------------------|--------------------|

|         |                    |              |
|---------|--------------------|--------------|
| OPA_CHP | OPA positive input | Analog input |
| OPA_CHN | OPA negative input | Analog input |
| OPA_OUT | OPA output         | Analog input |

Table 8-9 CMP function settings

| Pin     | Configuration function | GPIO configuration                        |
|---------|------------------------|-------------------------------------------|
| CMP_CHP | CMP positive input     | Analog input                              |
| CMP_CHN | CMP negative input     | Analog input                              |
| CMP_OUT | CMP output             | Push-pull alternate output <sup>(1)</sup> |

Note: (1) When the CMP does external output, the GPIO is configured as multiplexed push-pull output, and when the CMP output is an internal channel, it is directly connected to the timer, so there is no need to configure the GPIO at the output.

Table 8-10 Other I/O function settings

| Pin    | Configuration function   | GPIO configuration                |
|--------|--------------------------|-----------------------------------|
| MCO    | Clock output             | Push-pull alternate output        |
| EXTI   | External interrupt input | Float, pull-up or pull-down input |
| LEDPWM | LED output               | Push-pull output                  |
| PIOC   | Input and output         |                                   |

Table 8-11 USB PD / type C controller

| USB PD pin | GPIO configuration                                                                                                  |
|------------|---------------------------------------------------------------------------------------------------------------------|
| CC1/CC2    | When the USB PD module is enabled, the alternate IO port is automatically connected to the internal PD transceiver. |

### 8.2.11 BC Function Configuration

The AFIO\_CR register includes the control bits for the UDM/UDP pin of the BC interface, the source voltage and the port pull-up mode. Before the set operation of the BC\_VSRC bit of UDM/UDP, it is necessary to operate the PUE[1:0] bits of UDM/UDP to set the pin to the pull-up mode, and this operation can enable the output of the BC protocol source voltage,  $V_{BC\_SRC}$ ; and the read operation of the BC\_CMPO bit of UDM/UDP can read the voltage of the pin with the BC protocol reference value  $V_{BC\_REF}$  status.

## 8.3 Register Description

### 8.3.1 GPIO Register Description

Unless otherwise specified, the registers of the GPIO must be operated as words (Operate these registers with 32 bits).

Table 8-12 GPIO-related registers list

| Name            | Access address | Description                              | Reset value |
|-----------------|----------------|------------------------------------------|-------------|
| R32_GPIOA_CFGLR | 0x40010800     | PA port configuration register low (0-7) | 0x44444444  |
| R32_GPIOB_CFGLR | 0x40010C00     | PB port configuration register low (0-7) | 0x44444444  |

|                 |            |                                                       |            |
|-----------------|------------|-------------------------------------------------------|------------|
| R32_GPIOC_CFGLR | 0x40011000 | PC port configuration register low (0-7)              | 0x44444444 |

It reads 0 to indicate that no locking is in effect, and reads 1 to indicate that locking is in effect.</p> <p>The write sequence for the lock key is: write 1 - write 0 - write 1 - read 0 - read 1. The last step is not necessary, but can be used to confirm that the lock key is active.</p> <p>Any error while writing the sequence will not enable the activation of the lock and the value of LCK[23:0] cannot be changed while the sequence is being</p> | 0           |

|        |      |    |                                                                                                                                                                                                                                                                   |   |
|--------|------|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
|        |      |    | written. After the lock is in effect, the port configuration can only be changed after the next reset.                                                                                                                                                            |   |
| [23:0] | LCKy | RW | (y=0-23), these bits are 1 to indicate locking the configuration of the corresponding port. These bits can only be changed before the LCKK is unlocked. The locked configuration refers to the configuration registers GPIOx_CFGLR, GPIOx_CFGHR and GPIOx_CFGHHR. | 0 |

Note: After the LOCK sequence is executed for the corresponding port bit, the configuration of the port bit will not be changed again until the next system reset.

### 8.3.1.8 GPIO Configuration Register Expansion (16-23) Bits (GPIOx\_CFGXR) (x=A/B/C)

## Chapter 9 Direct Memory Access Control (DMA)

Direct Memory Access Controller (DMA) provides a high-speed means of data transfer between peripherals and memory or between memory and memory without CPU intervention, data can be moved quickly through the DMA to save CPU resources for other operations.

Each channel of the DMA controller is dedicated to managing requests for memory access from one or more peripherals. There is also an arbiter to co-ordinate priorities between the channels.

### 9.1 Main Features

- 8 general-purpose independently configurable channels, with additional dedicated independent channels for USB and USB PD.
- Each channel is directly connected to a dedicated hardware DMA request and supports software triggering
- Support Buffer management with loop
- Request priority between multiple channels can be set by software programming (Very high, high, medium and low) and priority setting is determined by the channel number when equal (The lower the channel number the higher the priority)
- Support peripheral-to-memory, memory-to-peripheral, and memory-to-memory transfers
- Flash memory, SRAM, peripheral SRAM and HB peripherals can be used as access sources and targets
- Programmable number of data transfer bytes: up to 65535

### 9.2 Function Description

#### 9.2.1 DMA Channel Processing

##### 1) Arbitration priority

DMA requests generated by multiple independent channels are fed to the DMA controller via a logical or structure, and only one channel request is currently responded to. An arbiter inside the module selects the peripheral/memory access to be initiated based on the priority of the channel request.

In software management, the application can configure the priority level for each channel independently by setting the PL[1:0] bits of the DMA\_CFGRx register, including 4 levels: highest, high, medium and low. When the software setting levels are the same between channels, the module will be selected according to a fixed hardware priority, with the lower channel number having a higher priority than the higher one.

##### 2) DMA configuration

When the DMA controller receives a request signal, it accesses the requested peripheral or memory and establishes a data transfer between the peripheral or memory and the memory. It consists of the following 3 main operation steps.

- (1) Fetch data from the memory address indicated by the Peripheral Data Register or the Current Peripheral/Memory Address Register. The start address for the first transfer is the peripheral base address or memory address specified by the DMA\_PADDRx or DMA\_MADDRx registers.
- (2) Store data to the memory address indicated by the Peripheral Data Register or the Current Peripheral/Memory Address Register, and the start address for the first transfer is the peripheral base address or memory address specified by the DMA\_PADDRx or DMA\_MADDRx registers.
- (3) Performs a decrement operation of the value in the DMA\_CNTRx register, which indicates the number of

operations currently outstanding for transfer.

Each channel includes 3 types of DMA data transfer methods.

- Peripheral to memory (MEM2MEM=0, DIR=0)
- Memory to peripheral (MEM2MEM=0, DIR=1)
- Memory to memory (MEM2MEM=1)

*Note: The memory-to-memory mode does not require a peripheral request signal. After configuring this mode (MEM2MEM=1), the channel is turned on (EN=1) to start data transfer. This mode does not support cyclic mode.*

The configuration process is as follows.

- 1) Set the first address of the peripheral register or the memory data address in the memory-to-memory mode (MEM2MEM=1) in the DMA\_PADDRx register. This address will be the source or destination address for data transfer when a DMA request occurs.
- 2) Set the memory data address in the DMA\_MADDRx register. When a DMA request occurs, the transferred data will be read from or written to this address.
- 3) Set the amount of data to be transferred in the DMA\_CNTRx register. This value is decremented after each data transfer.
- 4) Set the priority of the channel in the PL[1:0] bits of the DMA\_CFGRx register.
- 5) Set the direction of data transfer, cyclic mode, incremental mode for peripheral and memory, data width for peripheral and memory, transfer halfway, transfer complete, and transfer error interrupt enable bits in the DMA\_CFGRx register.
- 6) Set the ENABLE bit of the DMA\_CCRx register to start channel x.

*Note: The DMA\_PADDRx/DMA\_MADDRx/DMA\_CNTRx registers and the direction of data transfer (DIR), cyclic mode (Location), and incremental mode of peripherals and memory (MINC/PINC) control bits in the DMA\_CFGRx register can be configured to write only when the DMA channel is turned off.*

### 3) Circular mode

Setting CIRC position 1 of the DMA\_CFGRx register enables the cyclic mode function for channel data transfers. In cyclic mode, when the number of data transfers becomes 0, the contents of the DMA\_CNTRx register are automatically reloaded to its initial value, and the internal peripheral and memory address registers are reloaded to the initial address values set by the DMA\_PADDRx and DMA\_MADDRx registers, and DMA operation will continue until the channel is turned off or the DMA mode is turned off.

### 4) DMA processing status

- Transfer half: It corresponds to the hardware setting of HTIFx bit in DMA\_INTFR register. The DMA transfer bytes half flag will be generated when the number of DMA transfers is reduced to less than half of the initial set value, and an interrupt will be generated if HTIE is set in the DMA\_CCRx register. The hardware uses this flag to alert the application that it can prepare for a new round of data transfers.
- Transfer completion: corresponds to the hardware setting of the TCIFx bit in the DMA\_INTFR register. When the number of DMA transfer bytes decreases to 0, the DMA transfer completion flag will be generated, and if TCIE is set in the DMA\_CCRx register, an interrupt will be generated.
- Transfer error: corresponds to a hardware set of the TEIFx bit in the DMA\_INTFR register. Reading and writing a reserved address area will generate a DMA transfer error. At the same time the module hardware will automatically clear the EN bit of the DMA\_CCRx register corresponding to the channel where the error occurred, and the channel is turned off. If TEIE is set in the DMA\_CCRx register, an interrupt will be generated.

When the application queries the DMA channel status, it can first access the GIFx bit of the DMA\_INTFR register to determine which channel is currently experiencing a DMA event, and then process the specific DAM event content for that channel.

### 9.2.2 Programmable Total Data Transfer Size/Data Bit Width/Alignment

The total size of the data to be transferred per DMA channel round is programmable up to 65535 times, and the number of pending transfer bytes is indicated in the DMA\_CNTRx register. At EN=0, the set value is written, and at EN=1 when the DMA transfer channel is turned on, this register becomes a read-only attribute with a decreasing value after each transfer.

The transferred data fetch values of peripherals and memories support the address pointer auto-increment function with programmable pointer increments. The first transmitted data address they access is stored in the DMA\_PADDRx and DMA\_MADDRx registers. By setting the PINC bit or MINC position 1 of the DMA\_CFGRx register, the peripheral address self-increment mode or memory address self-increment mode can be enabled, respectively. PSIZE[1:0] sets the peripheral address fetch data size and address self-increment size. MSIZE[1:0] sets the memory address to take the data size and address self-increasing small, including three choices: 8-bit, 16-bit, 32-bit. The specific data transfer methods are listed in the following table.

Table 8-1 DMA transfer with different data bit widths (PINC=MINC=1)

| Source bit width | Objectives bit width | Transmission number | Source: address/data                             | Target: address/data                                             | Transfer operations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### 9.2.3 DMA Request Mapping

Figure 9-1 DMA request mapping

The DMA controller provides 8 channels, each of which corresponds to multiple peripheral requests. By setting the corresponding DMA control bits in the corresponding peripheral registers, the DMA function of each peripheral can be switched on or off independently, with the following correspondence.

| Peripheral | Channel1 | Channel 2 | Channel 3 | Channel 4 | Channel 5 | Channel 6 | Channel 7 | Channel 8 |
|------------|----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| ADC        | ADC      |           |           |           |           |           |           |           |
| SPI        |          | SPI_RX    | SPI_TX    |           |           |           |           |           |
| USART1     |          |           |           | USART1_T  | USART1_R  |           |           |           |

|        |               |               |               |                                           |          |               |                      |                               |

Note: This register can only be changed when EN=0 and cannot be written when EN=1.

## Chapter 10 Analog-to-digital Converter (ADC)

The ADC module contains a 12-bit successive approximation type analogue-to-digital converter. It supports 15 external channels and 1 internal signal source sampling source. Single conversion and continuous conversion of channels, automatic scan mode between channels, intermittent mode, external trigger mode and double sampling can be accomplished. The analog watchdog function allows monitoring whether the channel voltage is within the threshold range.

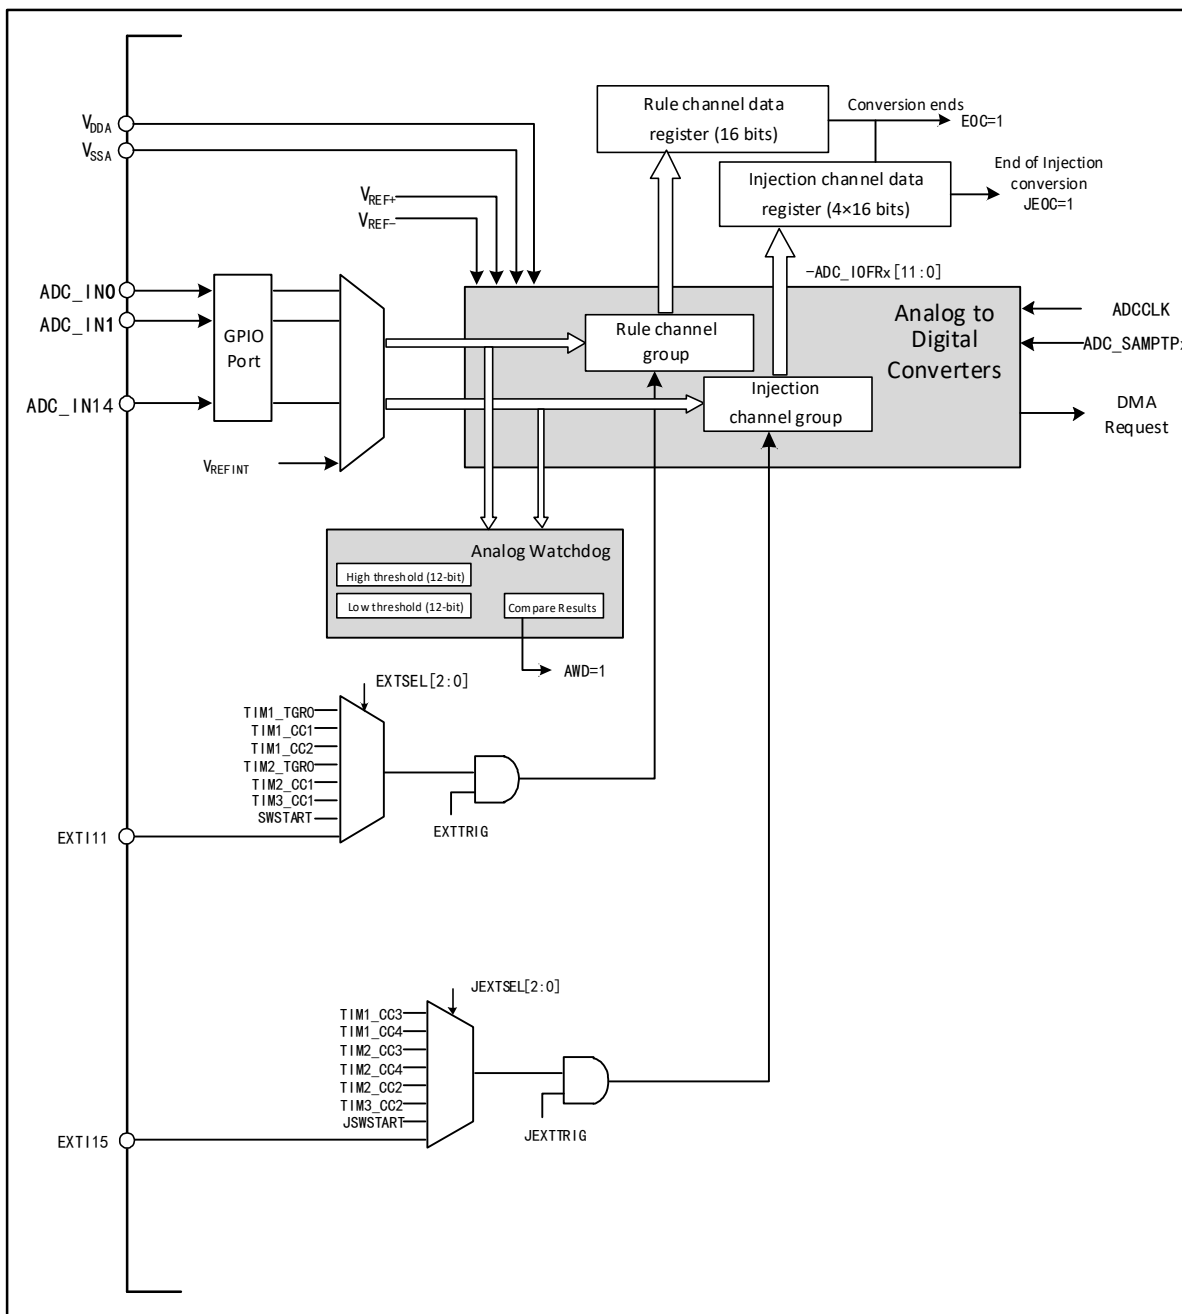

### 10.1 Main Features

- 12-bit resolution
- Supports 15 external channels and 1 internal signal sources for sampling
- Multiple sampling conversion methods for multiple channels: single, continuous, scan, trigger, intermittent, etc.
- Data alignment modes: left-aligned (Rule groups only), right-aligned
- Sampling time can be programmed separately by channel
- Both rule conversion and injection conversion support external triggering
- Analog watchdog to monitor channel voltage
- ADC channel input range:  $0 \leq V_{IN} \leq V_{DDA}$

## 10.2 Functional Description

### 10.2.1 Module Structure

Figure 10-1 ADC module block diagram

### 10.2.2 ADC Configuration

#### 1) Module power-up

An ADON bit of 1 in the ADC\_CTLR2 register indicates that the ADC module is powered up. When the ADC module enters the power-up state (ADON=1) from the power-down mode (ADON=0), a delay period  $t_{STAB}$  is required for the module stabilization time. After that, the ADON bit is written to 1 again and is used as the start signal for software to start the ADC conversion. By clearing the ADON bit to 0, the current conversion can be terminated and the ADC module placed in power-down mode, a state in which the ADC consumes almost no power.

## 2) Sampling clock

The module's register operations are based on the HCLK (HB bus) clock, whose conversion unit's clock reference ADCCLK is synchronized to HCLK and is configured by dividing the frequency in the CLK\_DIV[3:0] field of the ADC\_CTLR3 register.

## 3) Channel configuration

The ADC module provides 15 channel sampling sources. They can be configured into two types of conversion groups: regular groups and injection groups. to achieve a group conversion consisting of a series of conversions in any order on any number of channels.

Conversion group:

- Rule group: consists of up to 16 conversions. The rule channels and their conversion order are set in the ADC\_RSQRx register. The total number of conversions in the rule group should be written to L[3:0] in the ADC\_RSQR1 register.
- Injection group: consists of up to 4 conversions. The injection channels and the order of their conversions are set in the ADC\_ISQR register. The total number of conversions in the injection group should be written in JL[1:0] of the ADC\_ISQR register.

*Note: If the ADC\_RSQRx or ADC\_ISQR registers are changed during conversion, the current conversion is terminated and a new start signal is sent to the ADC to convert the newly selected group.*

1 internal channel:

- V<sub>REFINT</sub> internal reference voltage: connected to ADC\_IN15 channel.

## 4) Programmable sampling time

The ADC uses several ADCCLK cycles to sample the input voltage. The number of sampling cycles for a channel can be changed using the SMPx[2:0] bits in the ADC\_SAMPTR1 and ADC\_SAMPTR2 registers. Each channel can be sampled separately using a different time.

The total conversion time is calculated as follows.

$$T_{\text{CONV}} = \text{sampling time} + 13T_{\text{ADCCLK}}$$

The ADC's rule channel conversion supports the DMA function. The value of the rule channel conversion is stored in a data-only register, ADC\_RDATAR. To prevent the data in ADC\_RDATAR register from being fetched in time when multiple rule channels are converted in succession, the DMA function of ADC can be enabled. The hardware will generate a DMA request at the end of the conversion of a rule channel (EOC set) and transfer the converted data from the ADC\_RDATAR register to the user-specified destination address.

After the channel configuration of the DMA controller module is completed, write DMA position 1 of the ADC\_CTLR2 register to enable the DMA function of the ADC.

*Note: Injection group conversion does not support DMA function.*

## 5) Data alignment

The ALIGN bit in the ADC\_CTLR2 register selects the alignment of the ADC converted data storage. 12-bit data supports left-aligned and right-aligned modes.

The data register ADC\_RDATAR of the rule group channel holds the actual converted 12-bit digital value; while the data register ADC\_IDATARx of the injection group channel is the actual converted data minus the value written after the offset defined in the ADC\_IOFRx register, there will be positive and negative cases, so there are sign bits (SIGNB).

Note: Data left alignment applies only when rule groups are used.

### 10.2.3 External Trigger Source

The ADC conversion start event can be triggered by an external event. If the EXTTRIG or JEXTTRIG bits of the ADC\_CTLR2 register are set, the conversion of a rule group or injection group channel can be triggered by an external event, respectively. In this case, the configuration of EXTSEL[2:0] and JEXTSEL[2:0] bits determines the external event source for the rule group and injection group.

Table 10-1 External trigger sources for rule group channels

| EXTSEL[2:0] | Trigger source                      | Type                               |
|-------------|-------------------------------------|------------------------------------|
| 000         | TRGO event of timer 1               | Internal signal from on-chip timer |
| 001         | CC1 event of timer 1                |                                    |

|--|--|--|--|--------|--|
|  |  |  |  | method |  |
|--|--|--|--|--------|--|

*Note: The external trigger events for rule groups and injection groups are different, and the 'ACON' bit can only initiate rule group channel conversion, so the initiation events for rule group and injection group channel conversion are independent.*

### 1) Single-channel conversion mode

In this mode, only one conversion is executed for the current 1 channel. This mode performs conversion for the channel that is sorted 1st in the rule group or injection group, where it is initiated by setting ADON position 1 of the ADC\_CTLR2 register (For rule channels only) or can be initiated by external trigger (For rule channels or injection channels). Once the conversion of the selected channel is completed it will.

If the conversion is for a rule group channel, the conversion data is stored in the 16-bit ADC\_RDATAR register, the EOC flag is set, and an ADC interrupt is triggered if the EOCIE bit is set.

If the conversion is for an injection group channel, the conversion data is stored in the 16-bit ADC\_IDATAR1 register, the EOC and JEOC flags are set, and an ADC interrupt is triggered if the JEOCIE or EOCIE bit is set.

### 2) Single scan mode conversion

The ADC scan mode is entered by setting the SCAN bit of the ADC\_CTLR1 register to 1. This mode is used to scan a group of analog channels and perform a single conversion for all channels selected by ADC\_RSQRx register (For regular channels) or ADC\_ISQR (For injection channels) one by one, and the next channel in the same group is converted automatically when the current channel conversion is finished.

In the scan mode, there is a subdivision into triggered injection mode and automatic injection mode depending on the status of the IAUTO bit.

- Trigger injection

IAUTO bit is 0. When the trigger event of injection group channel conversion occurs during the scanning of rule group channels, the current conversion is reset and the sequence of injection channels is performed in a single scan, and the last interrupted rule group channel conversion is resumed after all selected injection group channel scanning conversions are completed.

If a rule channel start event occurs while the injection group channel sequence is currently being scanned, the injection group conversion is not interrupted, but the rule sequence conversion is executed again after the injection sequence conversion is completed.

*Note: When using triggered injection conversions, you must ensure that the interval between triggered events is longer than the injection sequence. For example, if the overall time to complete the conversion of the injection sequence takes 28 ADCCLK, then the minimum value of the event interval to trigger the injection channel is 29 ADCCLK.*

- Auto-injection

The IAUTO bit is set to 1, and conversion of the selected channel of the injection group is performed automatically after scanning all the channels selected by the rule group for conversion. This approach can be used to convert up to 20 conversion sequences in the ADC\_RSQRx and ADC\_ISQR registers.

In this mode, external triggering of the injection channel must be disabled (JEXTTRIG=0).

*Note: For ADC clock prescaler factor (CLK\_DIV[3:0]) of 4 to 8, 1 ADCCLK interval is automatically inserted when switching from rule conversion to injection sequence or from injection conversion to rule sequence; when ADC clock prescaler factor is 2, there is a delay of 2 ADCCLK intervals.*

### 3) Single intermittent mode conversion

The intermittent mode of the rule group or injection group is entered by setting the RDISCEN or IDISCEN bit of

the ADC\_CTLR1 register to 1. This mode differs from scanning a complete set of channels in scan mode, but divides a set of channels into multiple short sequences, and each external trigger event will perform a short sequence of scan transitions.

The length of the short sequence  $n$  ( $n \leq 8$ ) is defined in DISCNUM[2:0] of ADC\_CTLR1 register, when RDISCEN is 1, it is the interrupted mode of the rule group, and the total length to be converted is defined in RLEN[3:0] of ADC\_RSQR1 register; when IDISCEN is 1, it is the interrupted mode of the injection group, and the total length to be converted is defined in ILEN[1:0] of ADC\_ISQR register. It is not possible to set both the rule group and the injection group to intermittent mode.

Example of rule group intermittent mode.

RDISCEN=1, DISCNUM[2:0]=3, L [3:0]=8, channels to be converted = 1, 3, 2, 5, 8, 4, 10, 6

The 1st external trigger: conversion sequence is: 1, 3, 2

The 2nd external trigger: conversion sequence is: 5, 8, 4

The 3rd external trigger: conversion sequence is: 10, 6, while generating EOC events

The 4th external trigger: conversion sequence is: 1, 3, 2

Examples of intermittent patterns injected into groups.

IDISCEN=1, DISCNUM[2:0]=1, JL[1:0]=3, channel to be converted=1, 3, 2

The 1st external trigger: conversion sequence is: 1

The 2nd external trigger: the conversion sequence is: 3

The 3rd external trigger: conversion sequence is: 2, generating both EOC and JEOC events

The 4th external trigger: conversion sequence is: 1

*Note: 1. When converting a rule group or injection group in intermittent mode, the conversion sequence does not automatically start from the beginning when it ends. When all subgroups have been converted, the next trigger event starts the conversion of the first subgroup.*

*2. You cannot use auto-injection (LAUTO=1) and intermittent mode at the same time.*

*3. You cannot set intermittent mode for both rule groups and injection groups, and intermittent mode can only be used for a group of conversions.*

#### 4) Continuous conversion

In the continuous conversion mode, another conversion is started as soon as the previous ADC conversion is finished, and the conversion does not stop on the last channel of the selection group, but continues again from the first channel of the selection group. The startup events for this mode include an external trigger event and ADON position 1, which is required to set the CONT position 1 after startup.

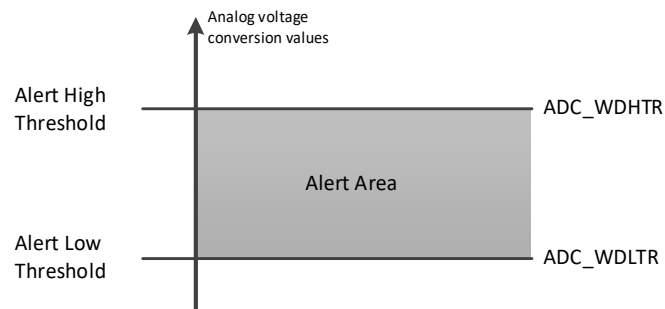

If a rule channel is converted, the conversion data is stored in the ADC\_RDATAR register, and the end-of-conversion flag EOC is set, generating an interrupt if EOCIE is set.

If an injection channel is converted, the conversion data is stored in the ADC\_IDATARx register, the end-of-injection-conversion flag JEOC is set, and an interrupt is generated if JEOCIE is set.

### 10.2.5 Analog Watchdog

The AWD analog watchdog status bit is set if the analog voltage being converted by the ADC is below the low threshold or above the high threshold. The threshold settings are located in the lowest 12 valid bits of the ADC\_WDHTR and ADC\_WDLTR registers. The AWDIE bit of the ADC\_CTLR1 register is set to allow the corresponding interrupt to be generated.

Figure 10-4 Analog watchdog threshold area

Configure the AWDSGL, AWDEN, JAWDEN and AWDCH[3:0] bits of the ADC\_CTLR1 register to select the channel for analog watchdog alerting, as related in the following table.

Table 10-4 Analog Watchdog channel selection

| Analog Watchdog alert channel     | ADC_CTLR1 register control bit |       |        |                              |
|-----------------------------------|--------------------------------|-------|--------|------------------------------|
|                                   | AWDSGL                         | AWDEN | JAWDEN | AWDCH[3:0]                   |
| No vigilance                      | Ignore                         | 0     | 0      | Ignore                       |
| All injection channels            | 0                              | 0     | 1      | Ignore                       |
| All rule channels                 | 0                              | 1     | 0      | Ignore                       |
| All injection and rule channels   | 0                              | 1     | 1      | Ignore                       |
| Single injection channel          | 1                              | 0     | 1      | Determine the channel number |
| Single rule channel               | 1                              | 1     | 0      | Determine the channel number |
| Single injection and rule channel | 1                              | 1     | 1      | Determine the channel number |

### 10.3 Register Description

Table 10-5 ADC-related registers list

| Name            | Access address | Description                                 | Reset value |
|-----------------|----------------|---------------------------------------------|-------------|
| R32_ADC_STATR   | 0x40012400     | ADC status register                         | 0x00000000  |

| [21:20] | JL[1:0]   | RW     | Inject the number of channels to be converted in the channel conversion sequence.<br>00-11: 1-4 conversions.                                                                                     | 0           |
| [19:15] | JSQ4[4:0] | RW     | The number of the 4th conversion channel in the injection sequence (0-15).<br><i>Note: The software writes and assigns the channel number (0-15) as the 4th in the sequence to be converted.</i> | 0           |
| [14:10] | JSQ3[4:0] | RW     | The number of the 3th conversion channel in the injection sequence (0-15).                                                                                                                       | 0           |
| [9:5]   | JSQ2[4:0] | RW     | The number of the 2th conversion channel in the injection sequence (0-15).                                                                                                                       | 0           |
| [4:0]   | JSQ1[4:0] | RW     | The number of the 1th conversion channel in the injection sequence (0-15).                                                                                                                       | 0           |

*Note: Unlike the regular conversion sequence, if the length of JL[1:0] is less than 4, the sequence order of conversion starts from (4 - JL).*

*For example, when JL[1:0]=3 (4 injected transitions in the sequencer), the ADC will convert channels in the following order: JSQ1[4:0], JSQ2[4:0], JSQ3[4:0], and JSQ4[4:0];*

*When JL[1:0]=2 (3 injected transitions in the sequencer), the ADC will convert the channels in the following order: JSQ2[4:0], JSQ3[4:0] and JSQ4[4:0];*

*When JL[1:0]=1 (2 injected conversions in the sequencer), the ADC converts the channels in the following order: first JSQ3[4:0], then JSQ4[4:0];*

*When JL[1:0] = 0 (1 injection conversion in the sequencer), the ADC will convert only the JSQ4[4:0] channels.*

*If ADCx\_ISQR[21:0]=10 00111 00011 00111 00010, the ADC will convert channels in the following order: JSQ2[4:0], JSQ3[4:0], and JSQ4[4:0], indicating that the scan conversions are performed in the following channel order: 7, 3, 7.*

*Note: Only available for watchdog channel 3.*

## Chapter 11 Touch Key Detection (TKEY)

The touch detection control (TKEY) unit, with the aid of the ADC module's voltage conversion function, implements the touch button detection function by converting the electrical capacity into a voltage quantity for sampling. The detection channels are alternate with the 15 external channels of the ADC and the touch button detection is achieved by the single conversion mode of the ADC module.

### 11.1 TKEY Functional Description

- TKEY on

The TKEY detection process requires the cooperation of the ADC module to carry out, so when using the TKEY function, you need to ensure that the ADC module is in the power-on state (ADON=1), then turn on the TKEY unit function by setting the TKENABLE position 1 of the ADC\_CTLR1 register.

TKEY only supports single channel conversion mode, configure the channel to be converted to the first of the ADC module's rule group sequence and the software initiates the conversion (Write the TKEY\_ACT\_DCG register).

*Note: When TKEY conversion is not performed, the ADC channel configuration conversion function can still be retained.*

Figure 11-1 TKEY operating timing diagram

- Programmable sampling times

The TKEY cell conversion requires a discharge using a number of ADCCLK clock cycles ( $t_{DISCHG}$ ) followed by a voltage sample by charging the channel over a number of ADCCLK cycles ( $t_{CHG}$ ). The number of charging cycles is the sum of the TKCGx[2:0] configuration values in the TKEY\_CHARGE1 and TKEY\_CHARGE2 registers plus the sum of the TKEY\_CHGOFFSET offsets, each channel can be adjusted separately with a different charge cycle to sample the voltage.

### 11.2 TKEY Operation Procedures

The TKEY detection is an extension of the ADC module and works by converting the capacity sensed by the hardware channel through "touch" and "non-touch" methods, and then converting the change in capacity to a voltage

through a configurable number of charge/discharge cycles. This is converted into a digital value by the ADC module. The ADC is configured to operate in a single pass single channel mode during sampling, with the TKEY\_ACT register "write operation" initiating a conversion as follows:

- 1) Initialize the ADC function, configure the ADC module as a single conversion module, set the ACON bit to 1 and wake up the ADC module. Set the TKENABLE position of ADC\_CTLR1 register to 1 and open the TKEY unit.
- 2) Set the channel to be converted, write the channel number to the first conversion position (ADC\_RSQR3[4:0]) in the ADC rule group sequence and set L[3:0] to 1.
- 3) Set the charging sample time for the channel, write the TKEY\_CHARGE<sub>x</sub> register to configure a different charging time for each channel.
- 4) Write the TKEY\_CHGOFFSET register to set the charge time offset of the channel (Valid in the lower eight bits) to adjust the charge time.
- 5) Write the TKEY\_ACT\_DCG register to set the discharge time (Valid in the lower eight bits) and to initiate a sample and conversion of the TKEY.
- 6) Wait for the EOC end of conversion flag position 1 in the ADC status register and read the ADC\_DR register to get the value of this conversion.
- 7) If the next conversion is required, repeat steps 2-6. If the channel charge sampling time does not need to be modified, step 3 or 4 can be omitted.

## 11.3 TKEY Register Description

Table 11-1 TKEY1-related registers list

| Name                | Access address | Description                            | Reset value |
|---------------------|----------------|----------------------------------------|-------------|
| R32_TKEY1_CHARGE1   | 0x4001240C     | TKEY charge sample time register 1     | 0x00000000  |

| Bit     | Name       | Access | Description     | Reset value |
|---------|------------|--------|-----------------|-------------|
| [31:16] | Reserved   | RO     | Reserved        | 0           |
| [15:0]  | DATA[15:0] | RO     | Converted data. | 0           |

Note: This register maps the ADC module's rule data register (ADC\_RDATAR).

## Chapter 12 Advanced-control Timer (ADTM)

The Advanced-control timer Module contains 2 powerful 16-bit auto-reload timers (TIM1/TIM2), which can be used to measure pulse width or generate pulses, PWM waves, etc. It is used in motor control, power supply, etc.

### 12.1 Main Features

The main features of the advanced-control timer (TIM1/TIM2) include.

- 16-bit auto-reload counter supporting incremental counting mode, decremental counting mode and incremental and decremental counting mode.
- 16-bit prescaler with dynamically adjustable crossover coefficients from 1 to 65536.
- Support four independent comparison capture channels.
- Each comparison capture channel supports multiple operating modes, such as: input capture, output comparison, PWM generation and single pulse output.
- Support complementary outputs with programmable dead time;
- Support external signals to control the timer.
- Support updating the timer after a defined period using a repeat counter.
- Support resetting the timer or placing it in the OK state using the brake signal.
- Support the use of DMA in multiple modes.
- Support incremental encoders.
- Support cascading and synchronization between timers.

### 12.2 Principle and Structure

This section deals with the internal construction of advanced-control timers.

#### 12.2.1 Overview

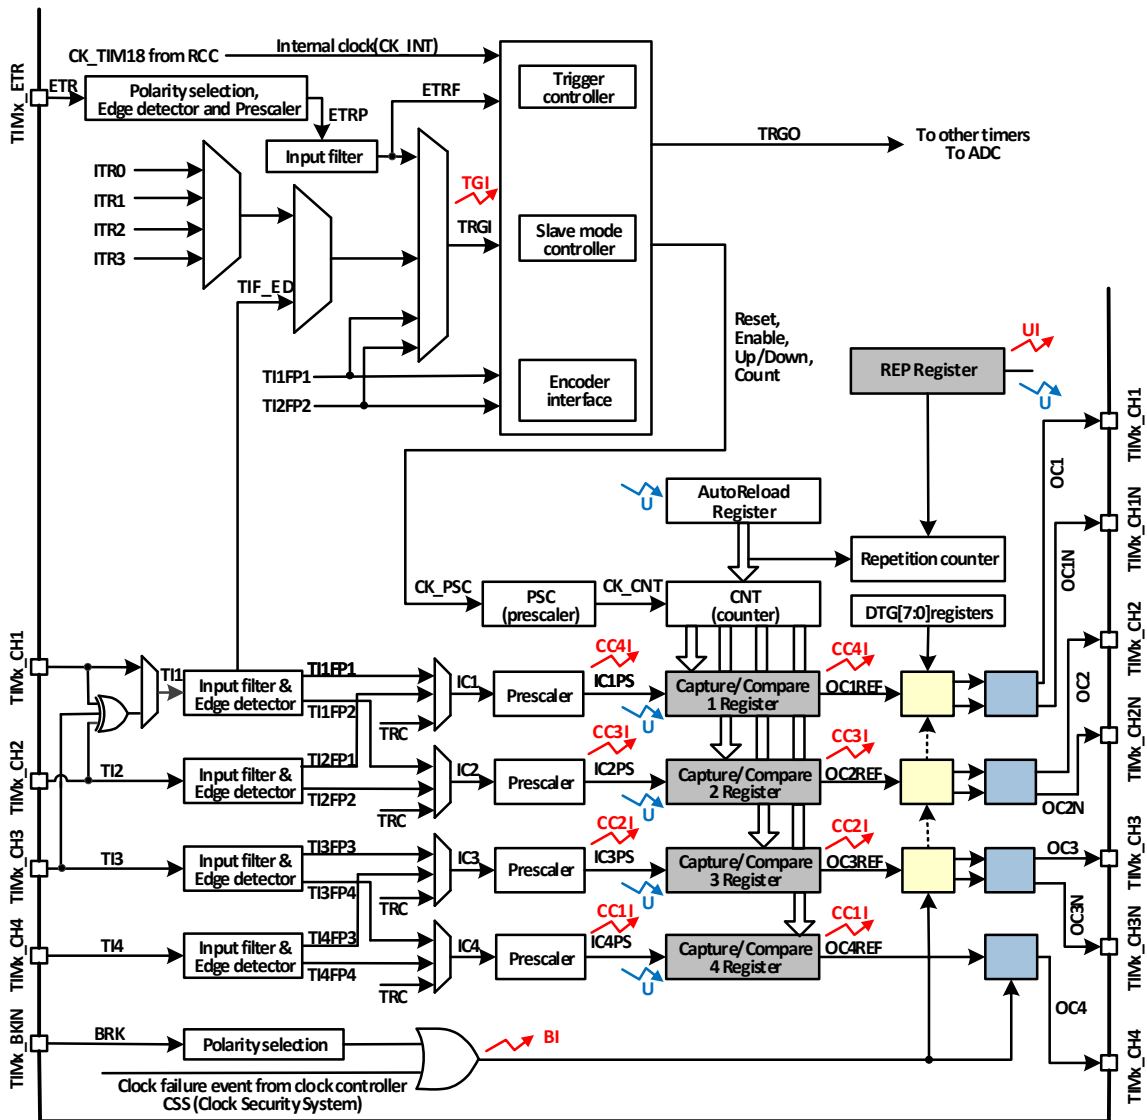

As shown in Figure 12-1, the structure of the advanced-control timer can be roughly divided into three parts, namely the input clock part, the core counter part and the compare capture channel part.

The advanced-control timer can be clocked from the HB bus clock (CK\_INT), from an external clock input pin (TIMx\_ETR), from other timers with clock output (ITRx), or from the input of the compare capture channel (TIMx\_CHx). These input clock signals become the CK\_PSC clock after various set filtering and dividing operations and are output to the core counter section. In addition, these complex clock sources can also be output as TRGO to other peripherals such as timers and ADCs.

The core of the advanced-control timer is a 16-bit counter (CNT), and the CK\_PSC is divided by a prescaler (PSC) to become the CK\_CNT and output to the CNT. An auxiliary counter counts the number of times the ATRLR reloads the initial value for the CNT and generates a specific event when the count reaches the number set in the Repeat Count Register (RPTCR).

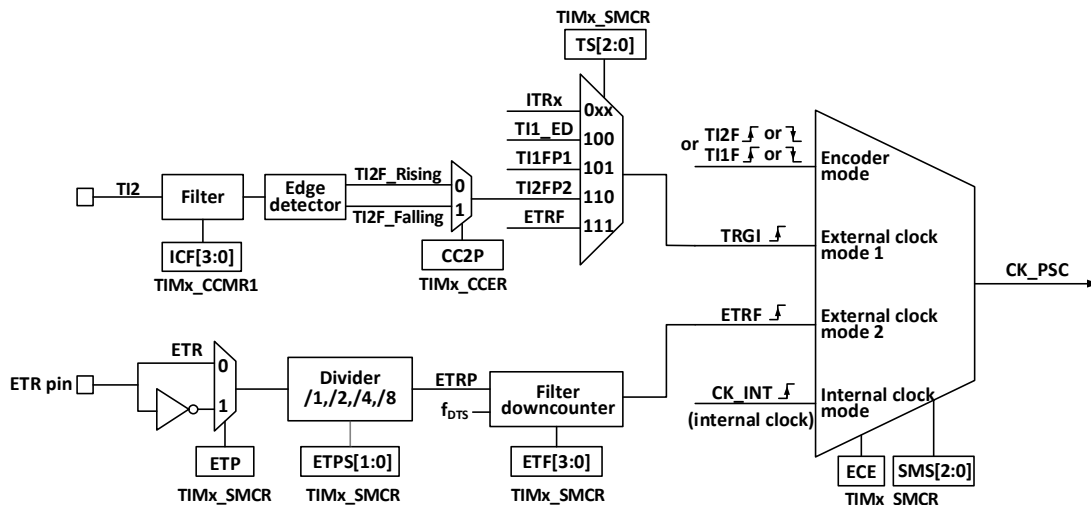

The advanced-control timer has four sets of compare capture channels, each of which can input pulses from exclusive pins or output waveforms to the pins, i.e., the compare capture channels support both input and output modes. The input of each channel of the compare capture register supports filtering, dividing and edge detection operations, and supports mutual triggering between channels, as well as providing a clock for the core counter CNT. Each compare capture channel has a set of compare capture registers (CHxCVR) that support comparison with the main counter (CNT) to output pulses.

Figure 12-1 Block diagram of advanced-control timer structure

## 12.2.2 Clock Input

Figure 10-2 Block diagram of CK\_PSC source for advanced-control timer

The advanced-control timer CK\_PSC has many clock sources and can be divided into 4 categories.

- 1) Route of external clock pin (ETR) input clock: ETR → ETRP → ETRF.
- 2) Internal HB clock input route: CK\_INT.
- 3) Route from the comparison capture channel pin (TIMx\_CHx): TIMx\_CHx → TIx → TIxFPx, this route is also used in encoder mode.
- 4) Inputs from other internal timers: ITRx.

The actual operation can be divided into 4 categories by determining the choice of input pulse for the SMS of the CK\_PSC source.

- 1) Selection of the internal clock source (CK\_INT).
- 2) External clock source mode 1.
- 3) External clock source mode 2.
- 4) Encoder mode.

All 4 clock source sources mentioned above can be selected by these 4 operations.

### 12.2.2.1 Internal Clock Source (CK\_INT)

If the SMS field is held at 000b to start the advanced-control timer, then it is the internal clock source (CK\_INT) that is selected as the clock. At this point CK\_INT is CK\_PSC.

### 12.2.2.2 External Clock Source Mode1

When the SMS domain is set to 111b, external clock source mode 1 is enabled. When external clock source 1 is enabled, TRGI is selected as the source of CK\_PSC. it is worth noting that the source of TRGI also needs to be selected by configuring the TS domain. the TS domain can select the following types of pulses as clock sources.

- 1) Internal trigger (ITRx, x is 0,1,2,3).
- 2) Comparison of the signal after capturing channel 1 through the edge detector (TI1F\_ED).
- 3) Comparison of signals TI1FP1, TI2FP2 of the capture channel.
- 4) The signal ETRF from the external clock pin input.

### 12.2.2.3 External Clock Source Mode2

Use external trigger mode 2 to count on every rising or falling edge of the external clock pin input. When the ECE position is set, the external clock source mode 2 is used. when using the external clock source mode 2, ETRF is selected as CK\_PSC. the ETR pin becomes ETRP after passing through the optional inverter (ETP), divider (ETPS), and then ETRF after passing through the filter (ETF).

With the ECE position bit and the SMS set to 111b, this is equivalent to the TS selecting ETRF as an input.

### 12.2.2.4 Encoder Mode

Setting the SMS to 001b, 010b, 011b will enable the encoder mode. Enabling encoder mode allows you to select a specific level in TI1FP1 and TI2FP2 to signal the output with another jump edge as the signal. This mode is used when an external encoder is used. Refer to Section 12.3.10 for specific functions.

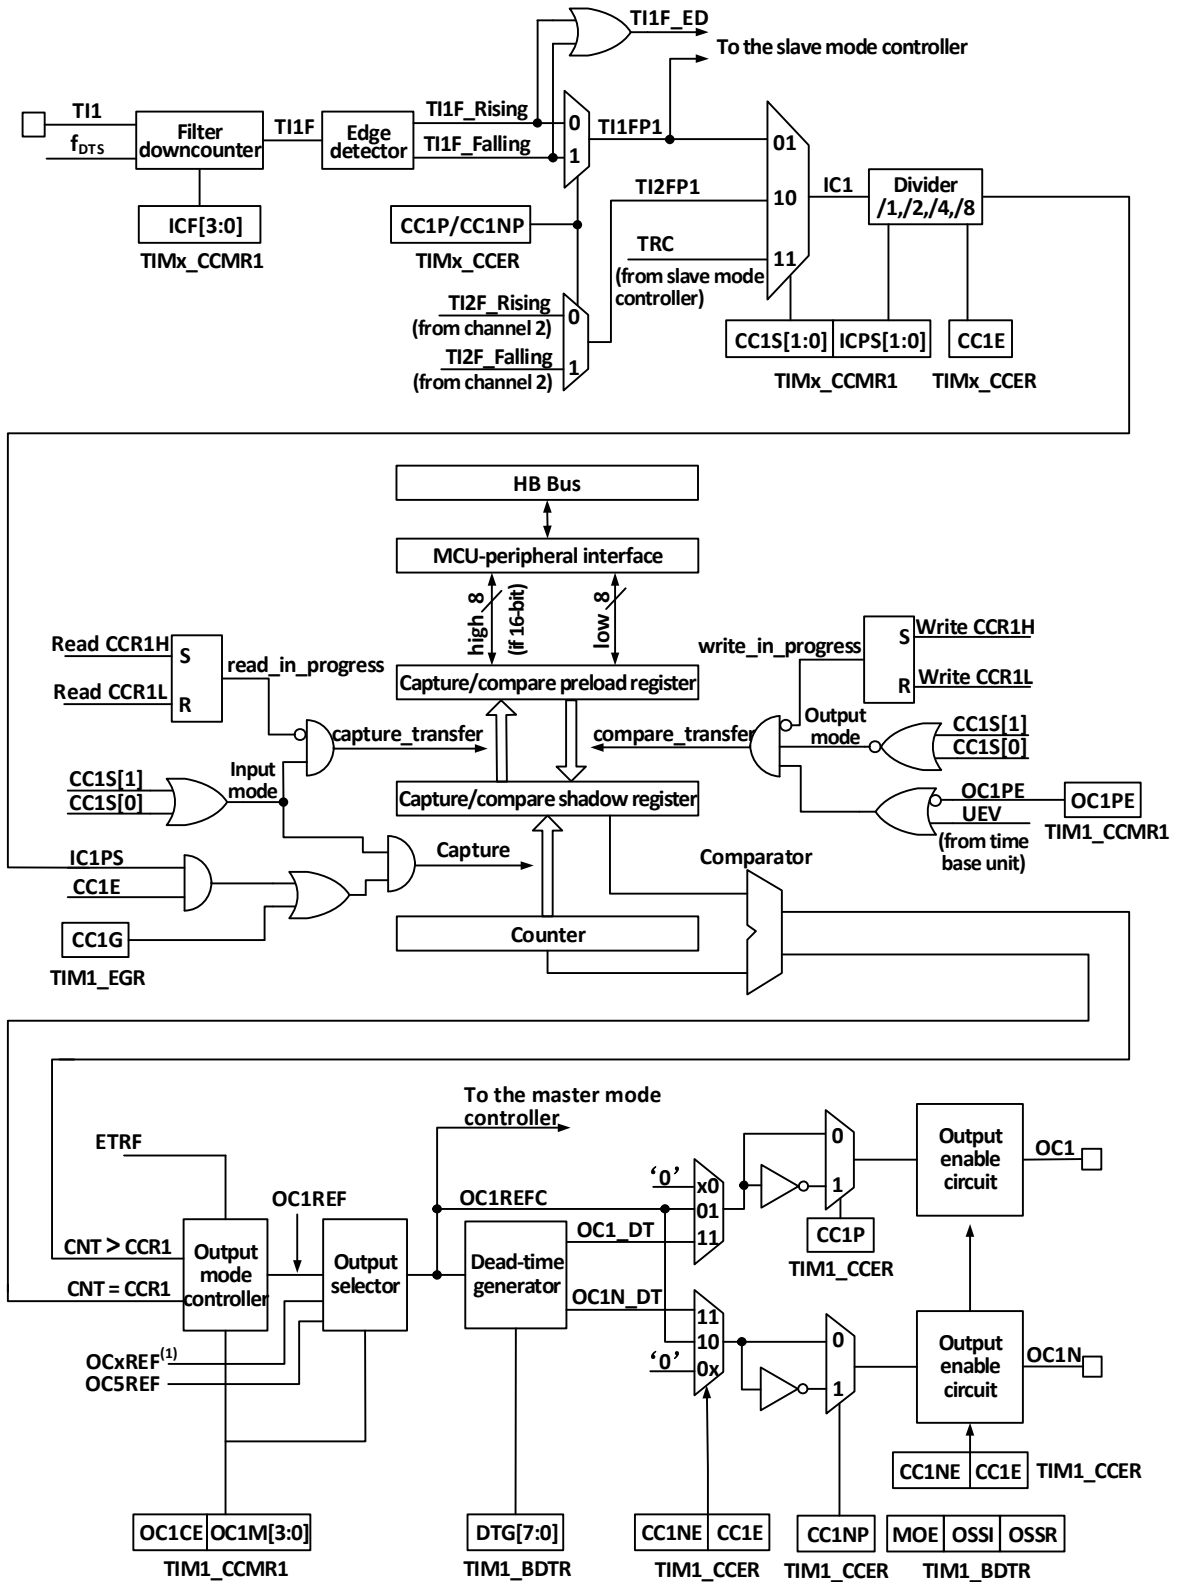

## 12.2.3 Counters and Peripherals

CK\_PSC is input to the prescaler (PSC) for dividing. the PSC is 16-bit and the actual dividing factor is equal to the value of R16\_TIMx\_PSC + 1. CK\_PSC goes through the PSC and becomes CK\_INT. changing the value of R16\_TIM1\_PSC does not take effect in real time, but is updated to the PSC after an update event. the update event includes a UG bit clear and reset. The core of the timer is a 16-bit counter (CNT). CK\_CNT is eventually fed to the CNT, which supports incremental count mode, decremental count mode, and incremental and decremental count modes, and has an Automatic Reload Register (ATRLR) that reloads the initial value for the CNT at the end of each count cycle. There is also an auxiliary counter that keeps track of the number of times the ATRLR reloads the initial value for the CNT and can generate a specific event when the number of times set in the Repeat Count Register (RPTCR) is reached.

## 12.2.4 Compare/Capture Channels and Peripherals

The core of the timer is the compare/capture register, which is complemented by digital filtering, frequency division and inter-channel multiplexing in the peripheral input section, comparator and output control in the output section.

Figure 12-3 Block diagram of the structure of the compare/capture channel

The structure block diagram of the compare/capture channel is shown in Figure 12-3. The signal is input from the channel x pin and optionally made as  $TIx$  (The source of  $TI1$  can be more than just  $CH1$ , see the structure block diagram of timer 10-1),  $TI1$  is passed through the filter ( $ICF[3:0]$ ) to generate  $TI1F$ , and then divided into  $TI1F\_Rising$  and  $TI1F\_Falling$  through the edge detector, these two signals are selected ( $CC1P$ ) to generate  $TI1FP1$ ,

TI1FP1 and TI2FP1 from channel 2 are sent together to CC1S to select to become IC1, which is sent to the comparison capture register after ICPS dividing.

The compare capture register consists of a preload register and a shadow register, and the read/write process operates only on the preload register. In capture mode, the capture occurs on the shadow register and is then copied to the preload register; in compare mode, the contents of the preload register are copied to the shadow register, and then the contents of the shadow register are compared to the core counter (CNT).

## 12.3 Function and Implementation

The implementation of the complex functions of the advanced-control timer are all achieved by the operation of the timer's compare capture channel, clock input circuit and counter and peripheral parts. The clock input to the timer can come from multiple clock sources, including the input to the compare capture channel. The operation of the compare capture channel and clock source selection directly determines its function. The compare capture channel is bidirectional and can operate in both input and output modes.

### 12.3.1 Counter Mode

#### Incremental counting modes

In incremental counting mode, the counter counts from 0 to the automatic reload value (the contents of the R16\_TIMx\_ATRLR register) and then starts counting again from 0 and generates a counter overflow event.

If a repeat counter is used, an update event (UEV) will be generated when the number of repeats of the incremental count reaches the number programmed in the repeat counter register plus one (R16\_TIMx\_RPTCR+1). Otherwise, an update event will be generated each time the counter overflows.

An update event will also be generated when setting the TIMx\_SWEVGR register to UG position 1 (Either by software or using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS position 1 in the R16\_TIMx\_CTLR1 register. This prevents the shadow register from being updated when a new value is written to the preload register. No update event will be generated until the UDIS bit is written to 0. However, both the counter and the prescaler counter will start counting from 0 again (While the prescaler ratio remains unchanged). In addition, if the URS bit (Update Request Select) in the R16\_TIMx\_CTLR1 register is set to 1, setting UG location 1 will generate the update event UEV, but will not set the UIF flag to 1 (So no interrupts or DMA requests will be sent). This way, if the counter is cleared to zero when a capture event occurs, no update interrupt and no capture interrupt will be generated at the same time.

When an update event occurs, all registers will be updated and the update flag (UIF bit in the R16\_TIMx\_INTFR register) will be set to 1 (Depending on the URS bit):

- 1) the contents of the R16\_TIMx\_RPTCR register will be reloaded in the repeat counter
- 2) the auto-reload shadow register will be updated with the preload value (R16\_TIMx\_ATRLR)
- 3) Preload value will be reloaded in the prescaler buffer (Contents of R16\_TIMx\_PSC register)

#### Decremental counting modes

In decrement count mode, the counter decrements from the auto reload value (Contents of the R16\_TIMx\_ATRLR register) to a count of 0, then re-counts from the auto reload value and generates a counter underflow event.

If a repeat counter is used, an update event (UEV) will be generated when the number of repeats of the decrement count reaches the number programmed in the repeat counter register plus one (R16\_TIMx\_RPTCR+1). Otherwise, an update event will be generated each time the counter overflows.

An update event will also be generated when setting the R16\_TIMx\_EGR register to UG position 1 (Either by

software or using the slave mode controller).

The UEV update event can be disabled by software by setting the UDIS location 1 in the R16\_TIMx\_CTLR1 register. This prevents the shadow register from being updated when a new value is written to the preload register. No update event will be generated until a 0 is written to the UDIS bit. However, the counter will start counting again from the current auto-reload value and the prescaler counter will start counting again from 0 (but the prescaler ratio remains unchanged).

In addition, if the URS bit (Update Request Select) in the R16\_TIMx\_CTLR1 register has been set to 1, setting UG location 1 will generate the update event UEV, but will not set the UIF flag to 1 (So no interrupts or DMA requests will be sent). In this way, if the counter is cleared to zero when a capture event occurs, no update interrupt and no capture interrupt will be generated at the same time.

When an update event occurs, all registers will be updated and the update flag (UIF bit in the R16\_TIMx\_INTFR register) will be set to 1 (Depending on the URS bit):

- 1) The contents of the R16\_TIMx\_RPTCR register will be reloaded in the repeat counter
- 2) the preload value (Contents of the R16\_TIMx\_PSC register) will be reloaded in the buffer of the prescaler
- 3) The auto-reload active register will be updated with the preload value (Contents of the R16\_TIMx\_ATRLR register).

*Note: The Auto Reload register will be updated before the counter is reloaded, so that the next count cycle is the new cycle length we want.*

### **Center alignment mode (Incremental/decremental counting)**

In center aligned mode, the counter counts from 0 to the auto-reload value (Contents of the R16\_TIMx\_ATRLR register) -1, generating a counter overflow event; it then counts down from the auto-reload value to 1 and generates a counter underflow event. After that the count starts again from 0.

The center-aligned mode is valid when the CMS bit in the R16\_TIMx\_CTLR1 register is not "00". When a channel is configured in output mode, its output compare interrupt flag will be set to 1 in the following modes: counter decrement count (Center-aligned mode 1, CMS="01"), counter increment count (Center-aligned mode 2, CMS="10") and Counter Incremental/Decremental Counting (Centre Alignment Mode 3, CMS="11").

In this mode, the DIR direction bit of the R16\_TIMx\_CTLR1 register is not writable, but is updated by hardware and indicates the current counter direction.

An update event is generated each time a counter overflow and underflow occurs, or an update event can also be generated by setting UG position 1 in the R16\_TIMx\_SWEVGR register (Either by software or using the slave mode controller). In this case the counter as well as the prescaler counter will start counting again from 0.

The UEV update event can be disabled by software by setting the UDIS position 1 in the R16\_TIMx\_CTLR1 register. This prevents the shadow register from being updated when a new value is written to the preload register. No update event will be generated until the UDIS bit is written to 0. However, the counter will still count incrementally and decrementally according to the current auto-reload value.

In addition, if the URS bit (Update Request Select) in the R16\_TIMx\_CTLR1 register has been set to 1, setting UG location 1 will generate a UEV update event, but will not set the UIF flag to 1 (And therefore no interrupts or DMA requests will be sent). This way, if the counter is cleared to zero when a capture event occurs, no update interrupt and no capture interrupt will be generated at the same time.

When an update event occurs, all registers will be updated and the update flag (UIF bit in the R16\_TIMx\_INTFR register) will be set to 1 (Depending on the URS bit):

- 1) the contents of the R16\_TIMx\_RPTCR register will be reloaded in the repeat counter
- 2) the preload value (Content of the R16\_TIMx\_PSC register) will be reloaded in the buffer of the prescaler
- 3) The auto-reload active register will be updated with the preload value (Contents of the R16\_TIMx\_ATRLR

register). Note that if the update operation is triggered by a counter overflow, the auto-reload register is updated before the counter is reloaded, so that the next count cycle is the new cycle length we want (the counter is reloaded with the new value).

### 12.3.2 Input Capture Mode

The input capture mode is one of the basic functions of the timer. The principle of input capture mode is that a capture event occurs when a determined edge on the ICxPS signal is detected, and the current value of the counter is latched into the compare capture register (R16\_TIMx\_CHCTLRx). When a capture event occurs, CCxIF (In R16\_TIMx\_INTFR) is set, and if an interrupt or DMA is enabled, the corresponding interrupt or DMA is also generated. If CCxIF is already set when a capture event occurs, the CCxOF bit is set. CCxIF can be cleared by software, or by hardware by reading the compare capture register. CCxOF is cleared by software.

An example of channel 1 to illustrate the steps to use the input capture mode is as follows.

- 1) Configure the CCxS domain to select the source of the ICx signal. For example, set to 10b and select TI1FP1 as the source of IC1 instead of using the default setting, where the CCxS domain defaults to making the comparison capture module the output channel.
- 2) Configure the ICxF domain to set the digital filter for the TI signal. The digital filter will sample the signal at a determined frequency, a determined number of times, and then output a hop. This sampling frequency and number of times is determined by ICxF.
- 3) Configure the CCxP bit to set the polarity of the TIxFPx. For example, keeping the CC1P bit low and selecting rising edge jumps.
- 4) Configure the ICxPS domain to set the ICx signal to be the crossover factor between ICxPS. For example, keeping ICxPS at 00b, without crossover.
- 5) Configure the CCxE bit to allow capturing the value of the core counter (CNT) into the compare capture register. Set the CC1E bit.
- 6) Configure the CCxIE and CCxDE bits as needed to determine whether to allow enable interrupts or DMA.

This completes the comparison capture channel configuration.

When a captured pulse is input to TI1, the value of the core counter (CNT) is recorded in the compare capture register, CC1IF is set, and the CC1OF bit is set when CC1IF has been set before. If the CC1IE bit is set, then an interrupt is generated; if CC1DE is set, a DMA request is generated. An input capture event can be generated by software by writing the event generation register (TIMx\_SWEVGR).

### 12.3.3 Compare Output Mode

The compare output mode is one of the basic functions of a timer. The principle of the compare output mode is to output a specific change or waveform when the value of the core counter (CNT) agrees with the value of the compare capture register. The OCxM field (in R16\_TIMx\_CHCTLRx) and the CCxP bit (in R16\_TIMx\_CCER) determine whether the output is a definite high or low level or a level flip. The CCxIF bit is also set when a compare coherent event is generated, an interrupt is generated if the CCxIE bit is pre-set, and a DMA request is generated if the CCxDE bit is pre-set.

The steps to configure to compare output mode are as follows:

- 1) Configure the clock source and auto-reload value of the core counter (CNT);
- 2) Set the count value to be compared to the compare capture register (R16\_TIMx\_CHxCVR);
- 3) Setting the CCxIE bit if an interrupt needs to be generated;
- 4) Disable the preload register of the compare register by keeping OCxPE to 0;
- 5) Set the output mode, setting the OCxM field and the CCxP bit;
- 6) Enable the output, setting the CCxE bit;

7) Set the CEN bit to start the timer.

### 12.3.4 Forced Output Mode

The output pattern of the timer's compare capture channel can be forced by software to output a determined level without relying on comparison of the compare capture register's shadow register with the core counter.

This is done by setting OCxM to 100b, which forces OCxREF to low, or by setting OCxM to 101b, which forces OCxREF to high.

Note that by forcing OCxM to 100b or 101b, the comparison process of the internal core counters and compare capture registers is still going on, the corresponding flags are still set, and interrupts and DMA requests are still being generated.

### 12.3.5 PWM Input Mode

The PWM input mode is used to measure the duty cycle and frequency of PWM and is a special case of the input capture mode. The operation is the same as input capture mode except for the following differences: PWM occupies two compare capture channels and the input polarity of the two channels is set to opposite, one of the signals is set as trigger input and SMS is set to reset mode.

For example, to measure the period and frequency of the PWM wave input from TI1, the following operations are required.

- 1) Set TI1 (TI1FP1) to be the input of IC1 signal. Set CC1S to 01b.
- 2) Set TI1FP1 to rising edge active. Holding CC1P at 0.
- 3) Set TI1 (TI1FP2) as the input of IC2 signal. Set CC2S to 10b.
- 4) Select TI1FP2 to set to falling edge active. Set CC2P to 1.
- 5) Select TI1FP1 as the source of the clock source. set TS to 101b.
- 6) Set the SMS to reset mode, i.e. 100b.
- 7) Enables input capture. CC1E and CC2E are set.

Thus the value of compare capture register 1 is the period of the PWM, and the value of compare capture register 2 is its duty cycle.

### 12.3.6 PWM Output Mode

PWM output mode is one of the basic functions of the timer. PWM output mode is most commonly used to determine the PWM frequency using the reload value and the duty cycle using the capture comparison register. Set 110b or 111b in the OCxM field to use PWM mode 1 or mode 2, set the OCxPE bit to enable the preload register, and finally set the ARPE bit to enable automatic reload of the preload register. Since the value of the preload register can only be sent to the shadow register when an update event occurs, the UG bit needs to be set to initialize all registers before the core counter starts counting. In PWM mode, the core counter and the compare capture register are always comparing, and depending on the CMS bit, the timer is able to output edge-aligned or center-aligned PWM signals.

- Edge alignment

When edge alignment is used, the core counter is incremented or decremented, and in the PWM mode 1 scenario, OCxREF is high when the core counter value is greater than the compare capture register, and low when the core counter value is less than the compare capture register (e.g., when the core counter grows to the value of R16\_TIMx\_ATRLR and reverts to all zeros).

- Central alignment

When using the central alignment modes, the core counter runs in alternating incremental and decremental count modes, and OCxREF makes rising and falling jumps when the values of the core counter and the compare capture

register match. However, the comparison flags are set at different times in the three central alignment modes. When using the central alignment modes, it is best to generate a software update flag (Set the UG bit) before starting the core counter.

### 12.3.7 Complementary Outputs and Deadband

The comparison capture channel generally has two output pins (Comparison capture channel 4 has only one output pin) and can output two complementary signals (OCx and OCxN). OCx and OCxN can be independently set for polarity via the CCxP and CCxNP bits, independently set for output enable via CCxE and CCxNE, and independently set for output enable via the MOE, OIS, OISN, OSSI, and OSSR bits for deadband and other controls. Enabling the OCx and OCxN outputs simultaneously will insert a deadband, and each channel has a 10-bit deadband generator. OCx and OCxN are generated by the OCxREF association. If both OCx and OCxN are high active, then OCx is the same as OCxREF except that the rising edge of OCx is equivalent to OCxREF with a delay, and OCxN is the opposite of OCxREF in that its rising edge will have a delay relative to the falling edge of the reference signal. If the delay is greater than the effective output width, the corresponding pulse will not be generated.

The relationship between OCx and OCxN and OCxREF is illustrated in Figure 12-4, which shows the dead zone.

Figure 12-4 Complementary outputs and deadband

### 12.3.8 Brake Signal

When the brake signal is generated, the output enable signal and invalid level are modified according to the MOE, OIS, OISN, OSSI, and OSSR bits. However, OCx and OCxN will not be at the active level at any time. The source of the brake event can come from the brake input pin or it can be a clock failure event which is generated by the CSS (Clock Safety System).

After system reset, the brake function is disabled by default (MOE bit is low), and setting the BKE bit enables the brake function. The polarity of the input brake signal can be set by setting BKP, and the BKE and BKP signals can be written at the same time, and there is a delay of one HB clock before the actual writing, so you need to wait for one HB cycle to read the written value correctly.

At the presence of the selected level on the brake pin the system will generate the following actions.

- 1) The MOE bit is cleared asynchronously, setting the output to an invalid, idle or reset state, depending on the setting of the SOOI bit.
- 2) After the MOE has been cleared, each output channel outputs a level determined by OISx.
- 3) When using complementary outputs: the outputs are placed in a null state, depending on the polarity.
- 4) If the BIE is set, an interrupt is generated when the BIF is set; if the BDE bit is set, a DMA request is generated.
- 5) If the AOE is set, the MOE bit is automatically set at the next update event UEV.

### 12.3.9 Single Pulse Mode

Single pulse mode can be used to allow the microcontroller to respond to a specific event by causing it to generate a pulse after a delay, with the delay and width of the pulse programmable. Placing the OPM bit allows the core counter to stop when the next update event UEV is generated (Counter flips to 0).

As shown in Figure 10-5, a positive pulse of length  $T_{pulse}$  needs to be generated on OC1 after a delay  $T_{delay}$  at the beginning of a rising edge detected on the TI2 input pin.

Figure 12-5 Generation of single pulse

- 1) Set TI2 to trigger. Setting the CC2S field to 01b to map TI2FP2 to TI2; setting the CC2P bit to 0b to set TI2FP2 as rising edge detection; setting the TS field to 110b to set TI2FP2 as trigger source; setting the SMS field to 110b to set TI2FP2 to be used to start the counter.
- 2)  $T_{delay}$  is determined by the value of the Compare Capture Register, and  $T_{pulse}$  is determined by the value of the Auto Reload Value Register and the Compare Capture Register.

### 12.3.10 Encoder Mode

The encoder mode is a typical application of the timer and can be used to access the biphasic output of the encoder. The counting direction of the core counter is synchronized with the direction of the encoder's rotation axis, and each pulse output from the encoder will cause the core counter to add or subtract one. To use the encoder, set the SMS field to 001b (Count only on TI2 edge), 010b (Count only on TI1 edge) or 011b (Count on both TI1 and TI2 edges), connect the encoder to the input of comparison capture channels 1 and 2, and set a value for the reload value register, which can be set to a larger value. When in encoder mode, the internal compare capture register, prescaler, repeat count register, etc. of the timer are working normally. The following table shows the relationship between the counting direction and the encoder signal.

Table 12-1 Relationship between counting direction and encoder signal of timer encoder mode

| Counting effective edges  | The level of relative signals | TI1FP1 signal edge |                   | TI2FP2 signal     |                   |
|---------------------------|-------------------------------|--------------------|-------------------|-------------------|-------------------|
|                           |                               | Rising edge        | Falling edge      | Rising edge       | Falling edge      |
| Counting at TI1 edge only | high                          | Downward counting  | Upward counting   | No count          |                   |
|                           | low                           | Upward counting    | Downward counting |                   |                   |
| Counting at TI2 edge only | high                          | No count           |                   | Upward counting   | Downward counting |
|                           | low                           |                    |                   | Downward counting | Upward counting   |

|                                        |      |                      |                      |                      |                      |
|----------------------------------------|------|----------------------|----------------------|----------------------|----------------------|
|                                        |      |                      |                      | counting             | counting             |
| Double edge counting at<br>TI1 and TI2 | high | Downward<br>counting | Upward<br>counting   | Downward<br>counting | Downward<br>counting |
|                                        | low  | Upward<br>counting   | Downward<br>counting | Upward<br>counting   | Upward<br>counting   |

### 12.3.11 Synchronization of TIMx Timers and External Triggers

The timer can be synchronized with an external trigger in reset mode, gated mode and trigger mode.

#### Slave mode: reset mode

The counter and its prescaler can be reinitialized in response to a trigger input event; if the URS bit of the R16\_TIMx\_CTLR1 register is low, an update event UEV is generated; all preload registers (R16\_TIMx\_ATRLR, R16\_TIMx\_CHxCVR) are then updated.

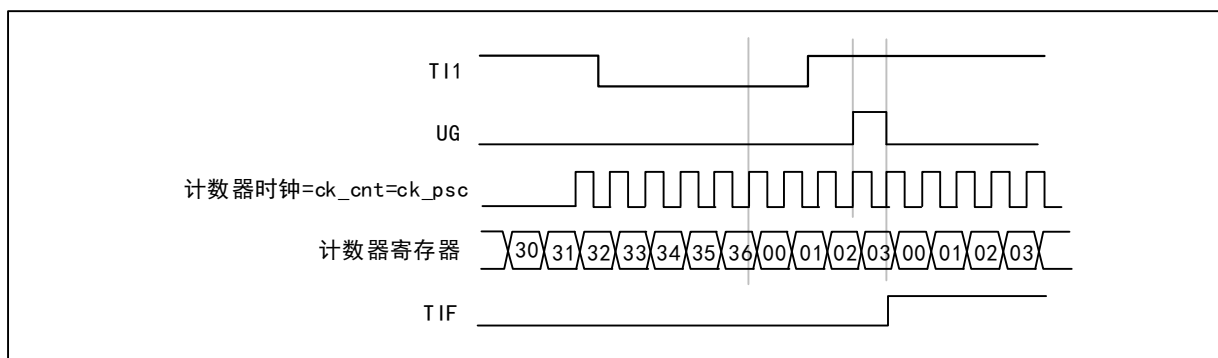

In the following example, the up counter is cleared to zero when a rising edge occurs on the TI1 input:

- 1) Configure channel 1 to detect the rising edge of TI1. Configure the input filter bandwidth (this example does not require any filter, so keep IC1F = 0000). There is no need to configure the capture divider as it is not used for trigger operation. the CC1S bit selects only the input capture source, i.e. CC1S=01 (In R16\_TIMx\_CCMR1). Write CC1P=0 and CC1NP='0' to the R16\_TIMx\_CCER register to verify polarity (Rising edge detection only).
- 2) Write SMS=100 to R16\_TIMx\_SMCFGR to configure the timer to reset mode; write TS=101 to R16\_TIMx\_SMCFGR to select TI1 as input source.
- 3) Write CEN=1 to R16\_TIMx\_CTLR1 to start the counter.

The counter counts using the internal clock and then runs normally, when there is a TI1 rising edge the counter clears and starts counting again from 0. At the same time, the trigger flag TIF position 1, after enabling interrupt or DMA, allows an interrupt or DMA request to be sent. (Depends on the TIE (Interrupt Enable) bit and TDE (DMA Enable) bit in the R16\_TIMx\_DMAINTENR register).

The diagram below shows the action when the auto-reload register R16\_TIMx\_ARR = 0x36. The delay between the rising edge of TI1 and the actual counter reset is caused by the resynchronization circuitry at the TI1 input.

Figure 12-6 Control circuit in reset mode

#### Slave mode: Gated mode

The level of the input signal enables the counter. In the following example, the counter counts up only when TI1 is low:

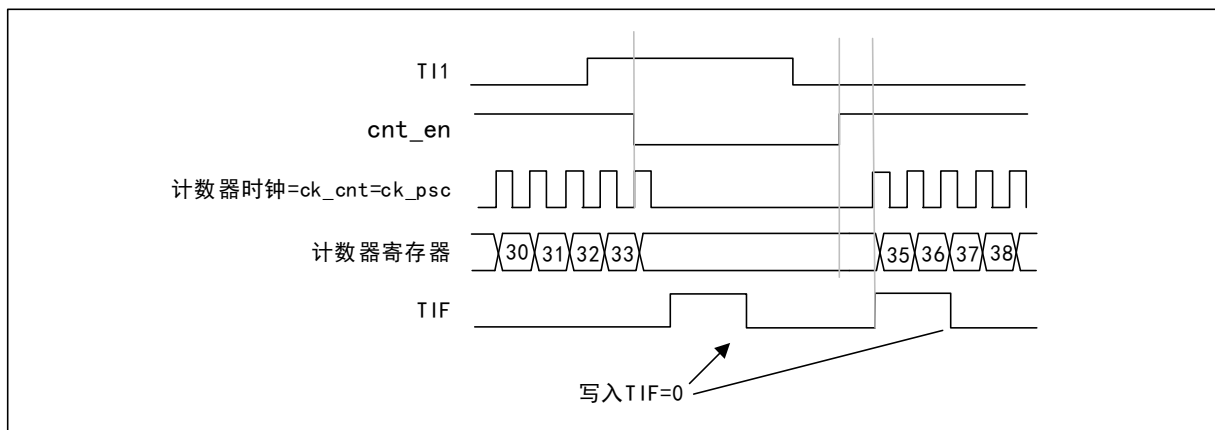

- 1) Configure channel 1 to detect a low level on TI1. Configure the input filter bandwidth (This example does not require any filter, so keep IC1F = 0000). There is no need to configure the capture divider as it is not used for trigger operation. the CC1S bit selects only the input capture source, i.e. CC1S=01 (In R16\_TIMx\_CCMR1). Write CC1P=1 and CC1NP='0' to the R16\_TIMx\_CCER register to verify polarity (Detect low level only).
- 2) Write SMS=101 to R16\_TIMx\_SMCFGR to configure the timer for gated mode; write TS=101 to

R16\_TIMx\_SMCFGR to select TI1 as input source.

3) Write CEN=1 to R16\_TIMx\_CTLR1 to start the counter. In gated mode, if CEN=0, the counter will not start regardless of the trigger input level.

As long as TI1 is low, the counter starts counting based on the internal clock and stops counting when TI1 goes high. When the counter starts or stops it sets TIF position 1 in R16\_TIMx\_INTFR. The delay between the rising edge of TI1 and the actual counter reset is caused by the resynchronization circuitry at the TI1 input.

Figure 12-7 Control circuit in gated mode

**Slave mode: Trigger mode**

An event on the selected input will enable the counter. In the following example, the up counter is activated when a rising edge occurs on the TI2 input:

1) Configure channel 2 to detect the rising edge of TI2. Configure the input filter bandwidth (This example does not require any filter, so keep IC2F = 0000). There is no need to configure the capture divider as it is not used for trigger operation. the CC2S bit selects only the input capture source by setting CC2S=01 (in R16\_TIMx\_CCMR1). Write CC2P=1 and CC2NP='0' to the R16\_TIMx\_CCER register to verify polarity (detect low level only)

2) Write SMS=110 to R16\_TIMx\_SMCFGR register to configure the timer to trigger mode; write TS=110 to R16\_TIMx\_SMCFGR register to select TI2 as input source.

When there is a rising edge of TI2, the counter starts counting driven by the internal clock, while TIF is set to 1. The delay between the rising edge of TI2 and the actual counter start is caused by the resynchronization circuitry at the TI2 input.

Figure 12-8 Control circuit in trigger mode

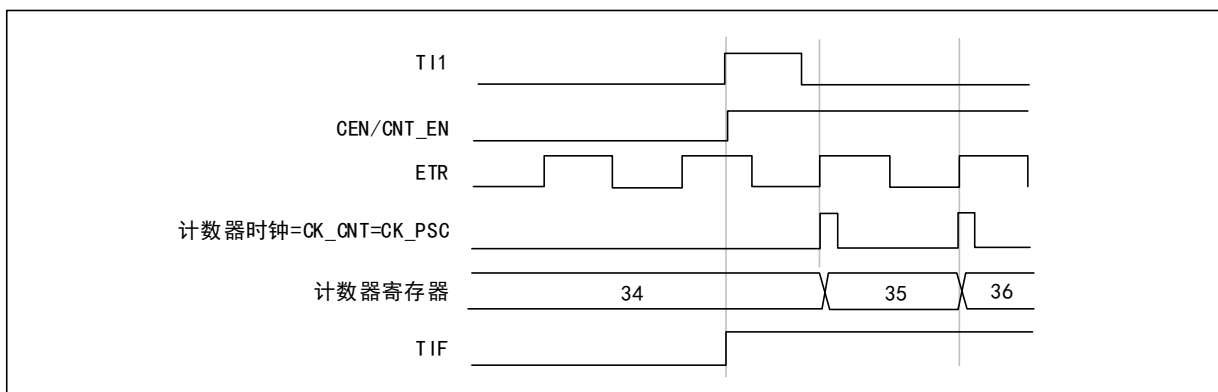

**Slave mode: external clock mode 2 + trigger mode**

External clock mode 2 can be used in conjunction with another slave mode in addition to external clock mode 1 and encoder mode. In this case, the ETR signal is used as an input to the external clock and the other input can be used as a trigger input in reset mode, gated mode or trigger mode. It is not recommended to select ETR as TRGI via the

TS bit of the R16\_TIMx\_SMCFGR register. in the following example, the up counter is incremented on each rising edge of ETR as soon as a rising edge occurs on TI1:

- 1) Configuring the R16\_TIMx\_SMCFGR register to configure the external trigger input circuit:
    - ETF=0000: no filtering;
    - ETPS=00: no prescaler used;
    - ETP=0: detect the rising edge of ETR, set ECE=1 to enable external clock mode 2.
  - 2) Configure channel 1 to detect the rising edge of TI:
    - IC1F=0000: no filtering;
    - no need to configure the capture divider as it is not used for trigger operation;
    - setting CC1S=01 in the R16\_TIMx\_CHCTLR1 register to select the input capture source;
    - set CC1P=0 in the R16\_TIMx\_CCER register to determine the polarity (Only rising edges are detected).
  - 3) Write SMS=110 to R16\_TIMx\_SMCFGR register to configure the timer to trigger mode. Write TS=101 to the R16\_TIMx\_SMCFGR register to select TI1 as the input source.
- When a rising edge occurs on TI1, the counter is enabled, TIF is set to 1 and the counter starts counting on the rising edge of ETR. the delay between the rising edge of the ETR signal and the actual counter reset is caused by the resynchronization circuit at the ETRP input.

Figure 12-9 Control circuit in external clock mode 2 + trigger mode

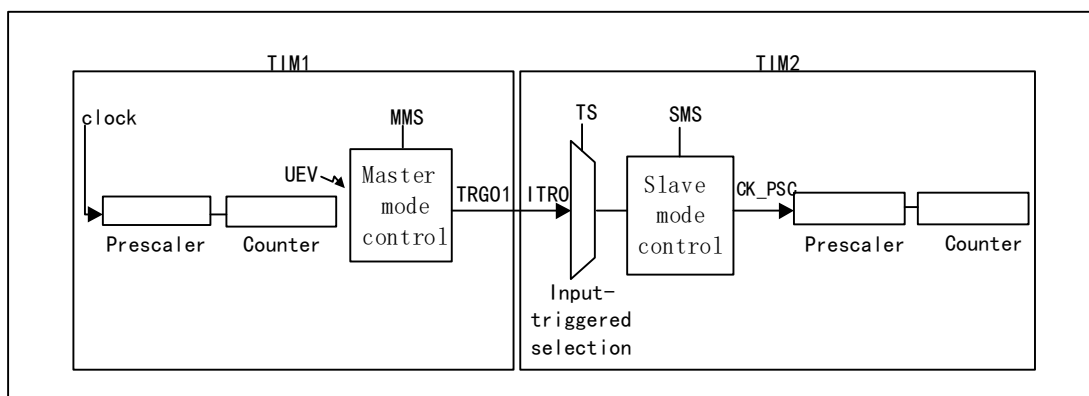

### 12.3.12 Timer Synchronization Mode

The TIMx timers are connected together from within to synchronize or cascade the timers. When a timer is configured in master mode, the counter of another timer configured in slave mode can be reset, started, stopped or clocked.

#### Using one timer as a prescaler for another timer

Figure 12-10 Master/slave timer example

For example, timer 1 can be configured as a prescaler for timer 2. To do this:

- 1) Configure Timer 1 in Master mode to output a periodic trigger signal every time an update event UEV occurs. If MMS=010 is written to R16\_TIM1\_CTLR2, TRGO1 will output a rising edge whenever an update event is generated.
- 2) To connect the TRGO1 output of Timer 1 to Timer 2, Timer 2 must be configured in slave mode, using ITR0 as the internal trigger. This can be selected via the TS bit in the R16\_TIM2\_SMCFGR register (Write TS=000).
- 3) The slave mode controller is then set to external clock mode 1 (Write SMS=111 in the R16\_TIM2\_SMCFGR register). In this way the clock for timer 2 will be supplied by the rising edge of the periodic trigger signal of timer 1 (Corresponding to the counter overflow of timer 1).
- 4) Finally both timers must be enabled simultaneously by setting the corresponding CEN bits (R16\_TIMx\_CTLR1 register) of both timers to 1.

*Note: If the OCx signal of timer 1 is selected as trigger output (MMS=1xx), the rising edge of this signal will be used to drive the counter of timer 2.*

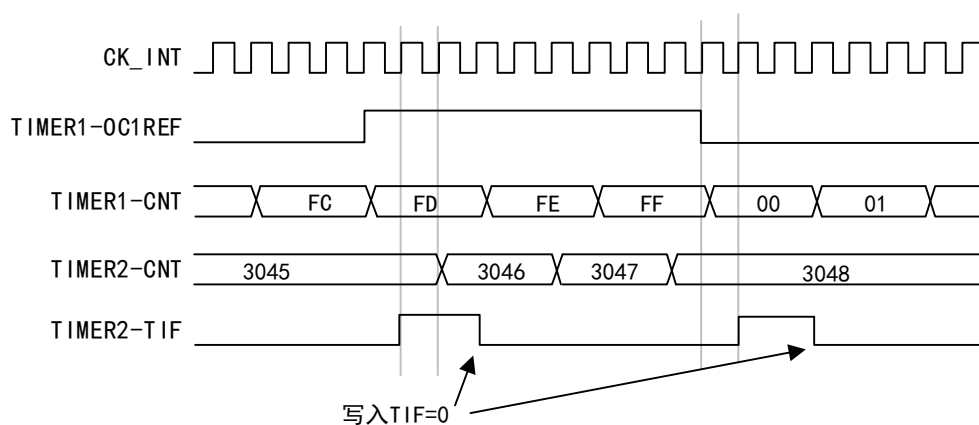

### Using one timer to enable another timer

In this example Timer 2 is enabled by comparing the output of Timer 1 with 1. Timer 2 counts according to the divided internal clock only when OC1REF of Timer 1 is high. The clock frequency of both counters is based on CK\_INT by prescaler performing a 3-way frequency ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

- 1) Configure timer 1 in main mode and send its output compare 1 reference signal (OC1REF) as trigger output (MMS=100 in R16\_TIM1\_CR2 register).
- 2) Configure Timer 1 for OC1REF waveform (R16\_TIM1\_CCMR1 register).
- 3) Configure Timer 2 to receive an input trigger from Timer 1 (TS=000 in R16\_TIM2\_SMCFGR register).
- 4) Configure Timer 2 to gated mode (SMS=101 in the R16\_TIM2\_SMCFGR register).
- 5) Enable Timer 2 by writing a "1" to the CEN bit (R16\_TIM2\_CTLR1 register).
- 6) Enable Timer 1 by writing "1" to the CEN bit (R16\_TIM1\_CTLR1 register).

*Note: The clock of Counter 2 is not synchronized with Counter 1, this mode only affects the counter enable signal of Timer 2.*

Figure 12-11 Gating Timer 2 using OC1REF of Timer 1

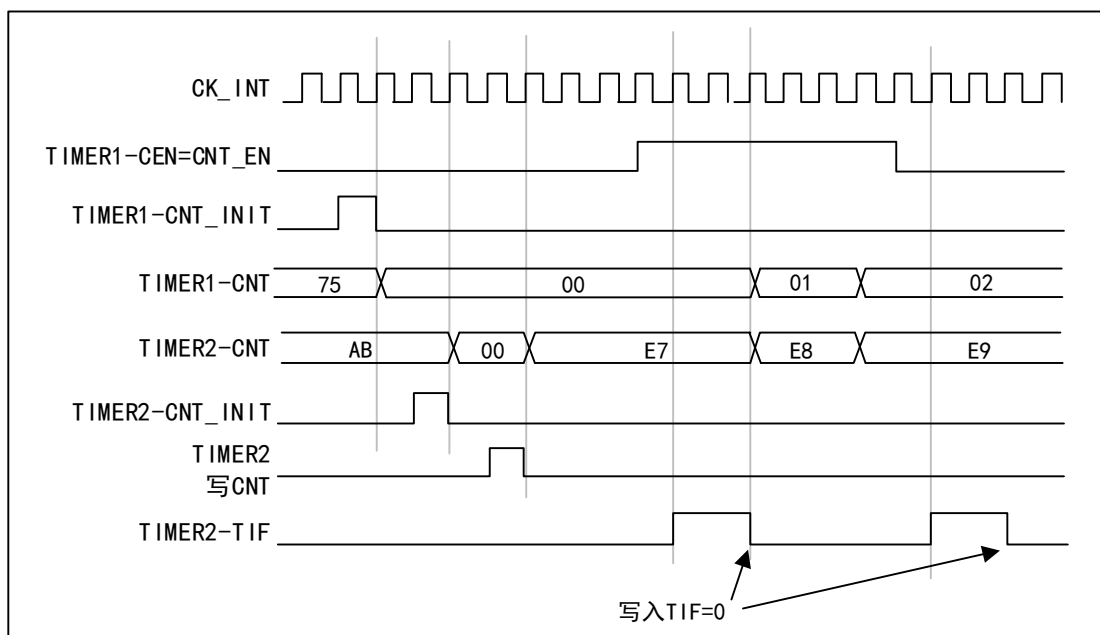

The counter and prescaler of timer 2 are not initialized before start-up. Therefore counting starts from the respective current value. Before starting Timer 1, both timers can be counted from the specified value by resetting them. This makes it possible to write any desired value into the timer counter. Both timers can be easily reset by software using the UG bit in the R16\_TIMx\_SWEVGR register.

In the next example, timer 1 is synchronized with timer 2. Timer 1 is in master mode and counts from 0. Timer 2 is in slave mode and counts from 0xE7. Both timers have the same prescale ratio. When timer 1 is disabled by writing "0" to the CEN bit in the R16\_TIM1\_CTLR1 register, timer 2 will stop:

- 1) Configure Timer 1 in main mode and send its output compare 1 reference signal (OC1REF) as the trigger output (MMS=100 in the R16\_TIM1\_CTLR2 register).
- 2) Configure Timer 1 for the OC1REF waveform (R16\_TIM1\_CHCTL1 register).
- 3) Configure Timer 2 to receive an input trigger from Timer 1 (TS=000 in R16\_TIM2\_SMCFGR register).
- 4) Configure Timer 2 to gated mode (SMS=101 in the R16\_TIM2\_SMCFGR register).
- 5) Reset Timer 1 by writing "1" to the UG bit (R16\_TIM1\_SWEVGR register).
- 6) Reset Timer 2 by writing "1" to the UG bit (R16\_TIM2\_SWEVGR register).
- 7) Initialize Timer 2 to 0xE7 by writing "0xE7" to Timer 2's counter (R16\_TIM2\_CNTL).
- 8) Enable Timer 2 by writing "1" to the CEN bit (R16\_TIM2\_CTLR1 register).
- 9) Enable Timer 1 by writing "1" to the CEN bit (R16\_TIM1\_CTLR1 register).
- 10) Stop Timer 1 by writing "0" to the CEN bit (R16\_TIM1\_CTLR1 register).

Figure 12-12 Gating Timer 2 using Timer 1's enable signal

### Using one timer to start another timer

This example uses the update event of Timer 1 to enable Timer 2. As soon as Timer 1 generates an update event, Timer 2 starts counting from the current value (Which may not be 0) according to the internal clock after dividing the frequency. When Timer 2 receives a trigger signal, its CEN bit is automatically set to 1 and the counter starts counting until a "0" is written to the CEN bit of the R16\_TIM2\_CTLR1 register and the counter stops counting. The clock frequency of both counters is based on CK\_INT and is divided by 3 through a prescaler ( $f_{CK\_CNT} = f_{CK\_INT} / 3$ ).

- 1) Configure timer 1 in main mode and send its update event (UEV) as trigger output (MMS=010 in R16\_TIM1\_CTLR2 register).
- (MMS=010 in R16\_TIM1\_CTLR2 register).
- 2) Configure the period of timer 1 (R16\_TIM1\_ATRLR register).
- 3) Configure Timer 2 to receive an input trigger from Timer 1 (TS=000 in the R16\_TIM2\_SMCFGR register).

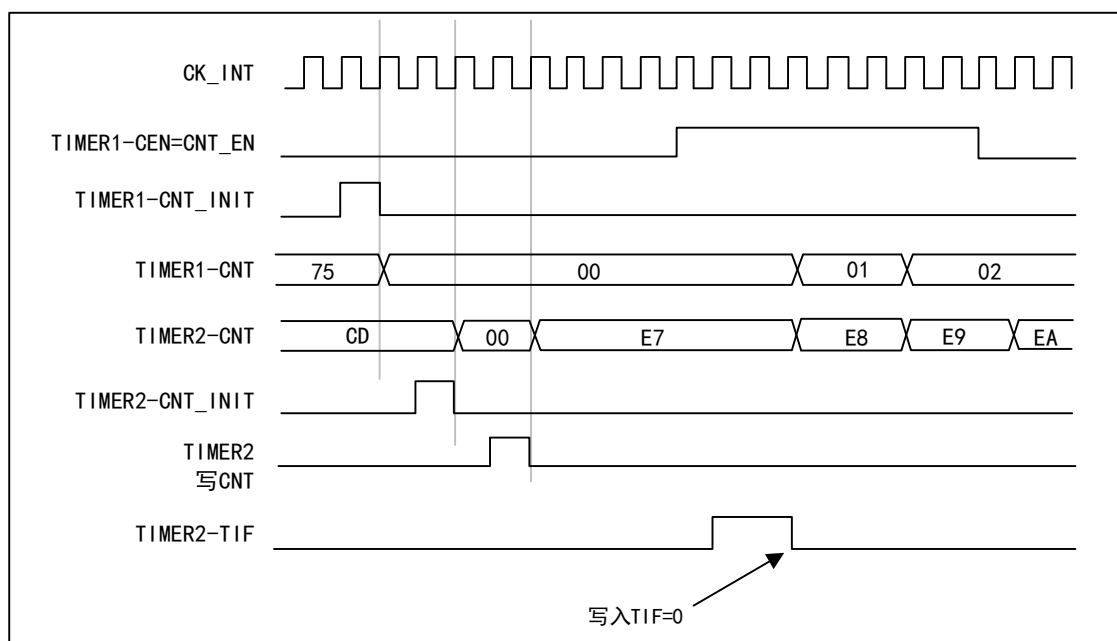

- 4) Configure Timer 2 to trigger mode (SMS=110 in the R16\_TIM2\_SMCFGR register).
- 5) Start Timer 1 by writing "1" to the CEN bit (R16\_TIM1\_CTLR1 register).

Figure 12-13 Triggering Timer 2 using Timer 1 update event

As shown in the example above, the user can initialize both counters before starting to count. Figure 12-14 shows the counting behaviour with the same configuration as Figure 12-13, except in trigger mode (SMS=110 in the R16\_TIM2\_SMCFGR register) rather than gated mode.

Figure 12-14 Triggering Timer 2 using Timer 1's enable signal

**Using one timer as a prescaler for another timer**

For example, timer 1 can be configured as a prescaler for timer 2. To do this:

- 1) Configure Timer 1 in main mode, sending its update event (UEV) as a trigger output (MMS=010 in the R16\_TIM1\_CTLR2 register). This will then output a periodic signal each time the counter overflows.
- 2) Configure the period of timer 1 (R16\_TIM1\_ATRLR register).
- 3) Configure Timer 2 to receive an input trigger from Timer 1 (TS=000 in the R16\_TIM2\_SMCFGR register).
- 4) Configure Timer 2 for external clock mode (SMS=111 in the R16\_TIM2\_SMCFGR register).
- 5) Start Timer 2 by writing a "1" to the CEN bit (R16\_TIM2\_CTLR1 register).

6) Timer 1 is started by writing "1" to the CEN bit (R16\_TIM1\_CTLR1 register).

**Synchronized start of 2 timers using an external trigger**

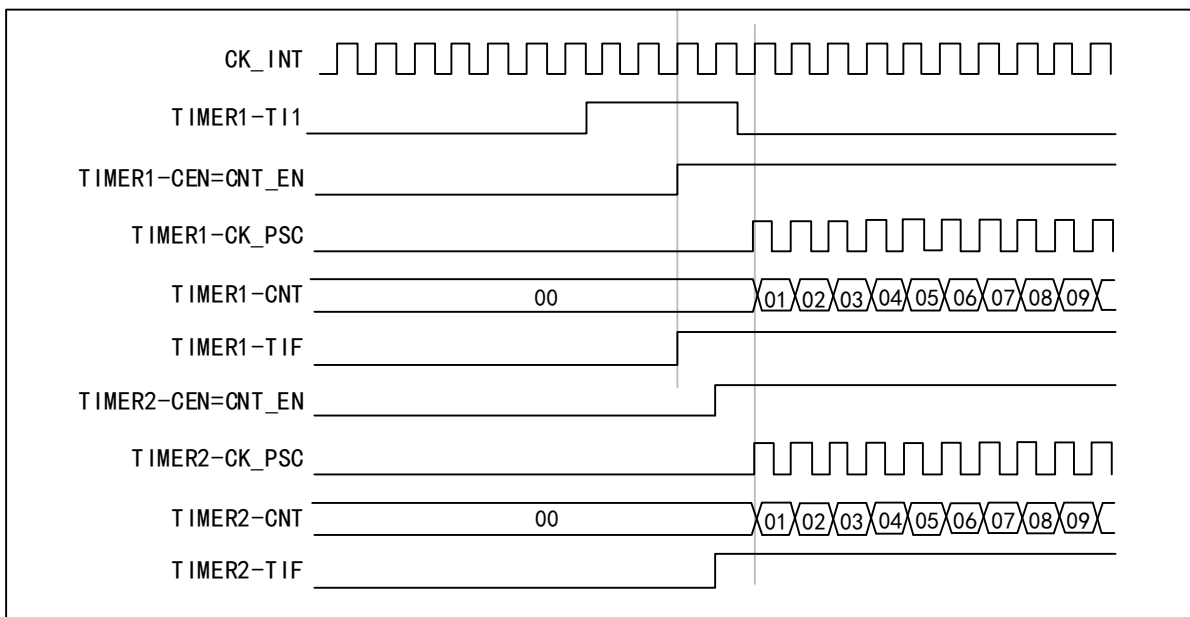

In this example, Timer 1 is enabled when there is a rising edge on the TI1 input of Timer 1, and Timer 2 is enabled at the same time as Timer 1. To ensure that the two counters are aligned, Timer 1 must be configured in master/slave mode (corresponding to TI1 as slave and Timer 2 as master):

- 1) Configure Timer 1 in Master mode, sending its enable signal as a trigger output (MMS=001 in the R16\_TIM1\_CTLR2 register).
- 2) Configure Timer 1 as Slave mode to receive the input trigger from TI1 (TS=100 in R16\_TIM1\_SMCFGR register).
- 3) Configure Timer 1 to trigger mode (SMS=110 in the R16\_TIM1\_SMCFGR register).
- 4) Configure Timer 1 to Master/Slave mode by writing MSM=1 (R16\_TIMx\_SMCR register).
- 5) Configure Timer 2 to receive an input trigger from Timer 1 (TS=000 in R16\_TIM2\_SMCFGR register).
- 6) Configure Timer 2 to trigger mode (SMS=110 in the R16\_TIM2\_SMCFGR register).

When a rising edge occurs on TI1 (Timer 1), both counters start counting synchronously according to the internal clock and both TIF flags are set to 1.

*Note: In this example, both timers are initialized (By setting their respective UG positions to 1) prior to start-up. Both counters count from 0, but an offset can easily be inserted between the two by writing to either counter register (R16\_TIMx\_CNT). It may be noted that the master/slave mode creates a delay between CNT\_EN and CK\_PSC for timer 1.*

Figure 12-15 Triggering Timer 1 and Timer 2 using Timer 1's TI1 input

Timers are capable of outputting clock pulses (TRGO) and also receiving inputs from other timers (ITRx). The source of ITRx (TRGO from other timers) is different for different timers. The timer internal trigger connections are shown in Table 12-2.

Table 12-2 TIMx internal trigger connections

| Slave timer | ITR0(TS=000) | ITR1(TS=001) | ITR2(TS=010) | ITR3(TS=011) |
|-------------|--------------|--------------|--------------|--------------|
| TIM1        | 0            | TIM2_TRGO    | 0            | 0            |

|      |           |   |   |   |
|------|-----------|---|---|---|
| TIM2 | TIM1_TRGO | 0 | 0 | 0 |
|------|-----------|---|---|---|

### 12.3.13 Debug Mode

When the system enters debug mode, the timer continues to run or stops according to the settings of the DBG module.

| [6:4] | MMS[2:0] | RW | Master mode selection: These 3 bits are used to select the synchronization information (TRGO) sent to the slave timer in master mode. The possible combinations are as follows.<br>000: The UG bit of the Reset-TIMx_EGR register is used as the trigger output (TRGO). In the case of a reset generated by a trigger input (from a mode controller in reset mode), there is a delay in the signal on TRGO relative to the actual reset.<br>001: Enable - The counter enable signal CNT_EN is used as a trigger output (TRGO). Sometimes it is necessary to start multiple timers at the same time or to control the enable from timers over a period of time. The counter enable signal is generated by the logical or of the trigger input signal in CEN control bit and gated mode. When the counter enable signal is controlled by a trigger input, there is a delay on TRGO unless master/slave mode is selected (See the description of the MSM bit in the TIMx_SMCR register).<br>010: Update - The update event is selected as a trigger input (TRGO). For example, the clock of a master timer may be used as a prescaler for a slave timer.<br>011: comparison pulse - on the occurrence of a capture or a successful comparison, when the CC1IF flag is to be set (Even if it is already high), the trigger output sends a positive pulse (TRGO).<br>100: The comparison-OC1REF signal is used as a trigger output (TRGO). | 0 |

|   |          |    |                                                                                                                                                                                                                                                                                                   |   |

### 12.4.7 Compare/Capture Control Register 1 (TIMx\_CHCTLR1) (x=1/2)

Offset address: 0x18

The channel can be used in input (Capture mode) or output (Compare mode), and the direction of the channel is defined by the corresponding CCxS bit. The other bits of this register have different roles in input and output modes. OCxx describes the function of the channel in output mode and ICxx describes the function of the channel in input mode.

### 12.4.8 Compare/Capture Control Register 2 (TIMx\_CHCTLR2) (x=1/2)

Offset address: 0x1C

The channel can be used in input (Capture mode) or output (Compare mode), and the direction of the channel is defined by the corresponding  $CCxS$  bit. The other bits of this register serve different purposes in input and output modes.  $OCxx$  describes the function of the channel in output mode and  $ICxx$  describes the function of the channel in input mode.

## Chapter 13 General-Purpose Timer (GPTM)

The general-purpose timer module contains a 16-bit auto-reloadable timer (TIM3), for measuring pulse width or generating pulses of a specific frequency, PWM waves, etc. It can be used in automation control, power supply, etc.

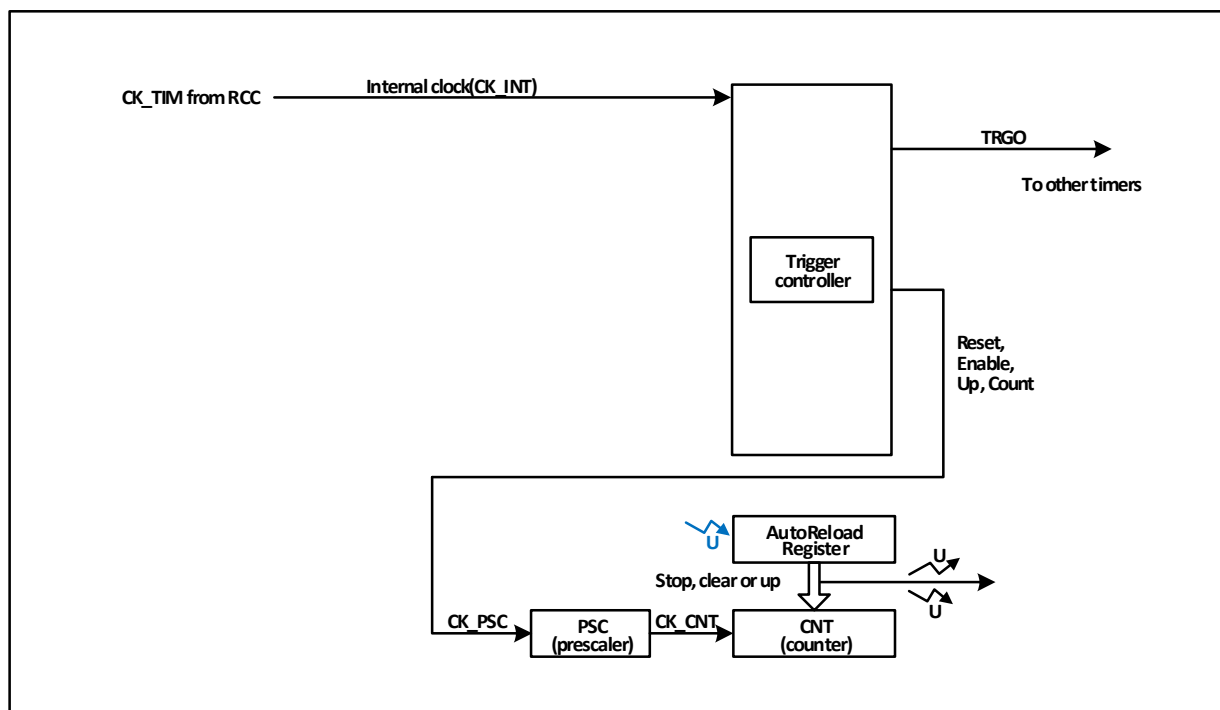

### 13.1 Main Features

The main features of the general-purpose timer include:

- 16-bit auto-reload counter, supports incremental counting mode
- 16-bit prescaler with dynamically adjustable crossover factor from 1 to 65536
- Support 2 independent comparison capture channels
- Each compare capture channel supports multiple operating modes, such as: input capture, output compare, PWM generation, and single pulse output
- Support external signal control timer

### 13.2 Principle and Structure

Figure 13-1 Block diagram of the structure of the general-purpose timer

#### 13.2.1 Overview

As shown in Figure 13-1, the structure of the general-purpose timer can be roughly divided into three parts, namely the input clock part, the core counter part and the compare capture channel part.

The clock for the general-purpose timer can come from the HB bus clock (CK\_INT), from the external clock input pin (TIMx\_ETR), from other timers with clock output (ITRx), and from the input of the compare capture channel (TIMx\_CHx). These input clock signals become CK\_PSC clocks after various set filtering and dividing operations, etc., and are output to the core counter section. In addition, these complex clock sources can also be output as TRGO

to other peripherals such as timers and ADCs.

The core of the general-purpose timer is a 16-bit counter (CNT). CK\_PSC is divided by a prescaler (PSC) to become cK\_CNT and then finally fed to the CNT, which supports incremental counting mode, decremental counting mode, and incremental and decremental counting mode, and has an auto-reload register (ATRLR) to reload the initialization value for the CNT at the end of each counting cycle.

The general-purpose timer has four sets of compare capture channels, each of which can input pulses from exclusive pins or output waveforms to pins, i.e., the compare capture channels support both input and output modes. The input of each channel of the compare capture register supports filtering, dividing, edge detection, and other operations, and supports mutual triggering between channels, and can also provide clock for the core counter CNT. Each comparison capture channel has a set of comparison capture registers (CHxCVR) that support comparison with the main counter (CNT) to output pulses.

### 13.2.2 Differences between General-Purpose Timer and Advanced-Control Timer

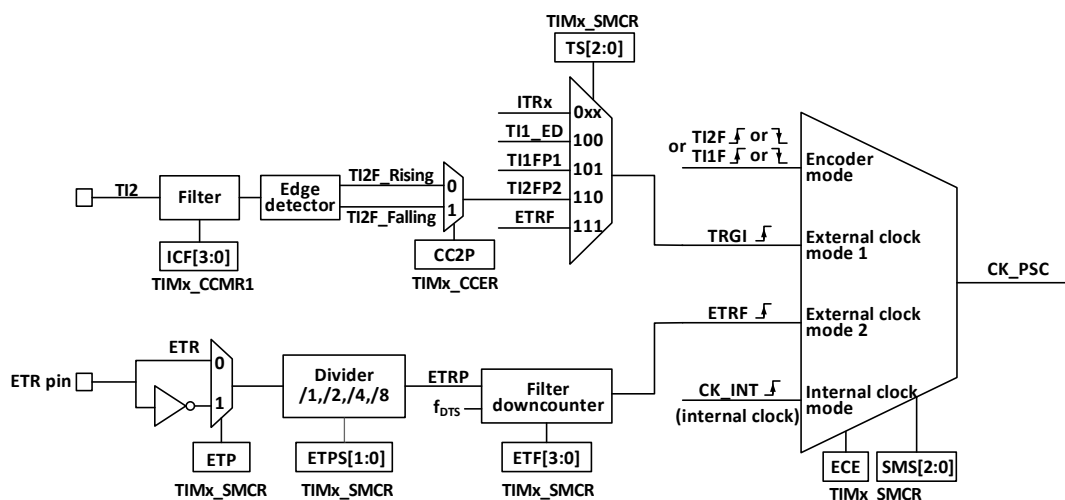

Compared to advanced-control timers, general-purpose timers lack the following features.

- 1) The general-purpose timer lacks a repeat count register for counting the count cycles of the core counter.
- 2) The comparison capture channel of the general-purpose timer lacks deadband generation and has no complementary output.
- 3) The general-purpose timer does not have a brake signal mechanism.
- 4) The general-purpose timer does not have encoder mode.

### 13.2.3 Clock Input

This section discusses the source of CK\_PSC. The clock source portion of the overall block diagram of the general-purpose timer is captured here.

Figure 13-2 General-purpose timer CK\_PSC source block diagram

The optional input clocks can be divided into 4 categories:

- 1) Route of the external clock pin (ETR) input: ETR → ETRP → ETRF.
- 2) Internal HB clock input route: CK\_INT.
- 3) Route from the compare capture channel pin (TIMx\_CHx): TIMx\_CHx → TIx → TIxFPx.
- 4) Input from other internal timers: ITRx.

The actual operation can be divided into 3 categories by determining the choice of input pulse for the SMS of the CK\_PSC source.

- 1) Selection of the internal clock source (CK\_INT).
- 2) External clock source mode 1.
- 3) External clock source mode 2.

All 3 clock source sources mentioned above can be selected by these 4 operations.

#### 13.2.3.1 Internal Clock Source (CK\_INT)

If the general-purpose timer is started when the SMS field is held at 000b, then it is the internal clock source (CK\_INT) that is selected as the clock. At this point CK\_INT is CK\_PSC.

#### 13.2.3.2 External Clock Source Mode 1

When the SMS domain is set to 111b, external clock source mode 1 is enabled. When external clock source 1 is enabled, TRGI is selected as the source for CK\_PSC. it is worth noting that the user also needs to select the source for TRGI by configuring the TS domain. the TS domain can select the following types of pulses as clock sources.

- 1) Internal trigger (ITRx, x is 0,1,2,3).
- 2) Comparison of the signal after capturing channel 1 through the edge detector (TI1F\_ED).
- 3) Comparison of signals TI1FP1, TI2FP2 of the capture channel.
- 4) The signal ETRF from the external clock pin input.

#### 13.2.4 Counters and peripherals

CK\_PSC is input to the prescaler (PSC) for dividing. the PSC is 16-bit and the actual dividing factor is equal to the value of R16\_TIMx\_PSC + 1. CK\_PSC goes through the PSC and becomes CK\_INT. changing the value of R16\_TIM1\_PSC does not take effect in real time, but is updated to the PSC after an update event. the update event includes a UG bit clear and reset.

#### 13.2.5 Compare/capture channels

The core of the compare capture channel, which is the core of the timer to achieve complex functions, is the compare capture register, supplemented by digital filtering, frequency division and inter-channel multiplexing in the peripheral input section, and comparator and output control in the output section. The structure block diagram of the compare capture channel is shown in Figure 13-3.

Figure 13-3 Block diagram of the structure of the comparison capture channel

The signal is input from the channel x pin and optionally made as TIx (The source of TI1 can be more than CH1, see block diagram 12-1 of the timer), TI1 is passed through the filter (ICF[3:0]) to generate TI1F, and then divided into TI1F\_Rising and TI1F\_Falling through the edge detector, these two signals are selected (CC1P) to generate TI1FP1, TI1FP1 and TI2FP1 from channel 2 are sent together to CC1S to select to become IC1, which is sent to the comparison capture register after ICPS dividing.

The compare capture register consists of a preload register and a shadow register, and the read/write process operates only on the preload register. In capture mode, the capture occurs on the shadow register and is then copied to the preload register; in compare mode, the contents of the preload register are copied to the shadow register, and then the contents of the shadow register are compared to the core counter (CNT).

## 13.3 Function and Implementation

The complex functions of a general-purpose timer are implemented by manipulating the timer's compare capture channel, clock input circuitry, and counter and peripheral components. The clock input to the timer can be derived from multiple clock sources including the input to the compare capture channel. The operation of the compare capture host channel and clock source selection directly determines its function. The compare capture channel is bidirectional and can operate in both input and output modes.

### 13.3.1 Counter Mode

#### Incremental counting mode

In incremental counting mode, the counter counts from 0 to the auto reload value (The contents of the R16\_TIMx\_ATRLR register), then counts again from 0 and generates a counter overflow event.

An update event will also be generated when setting the TIMx\_SWEVGR register to UG position 1 (Either by software or using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS position 1 in the R16\_TIMx\_CTLR1 register. This prevents the shadow register from being updated when a new value is written to the preload register. No update event will be generated until the UDIS bit is written to 0. However, both the counter and the prescaler counter will start counting from 0 again (While the prescaler ratio remains unchanged). In addition, if the URS bit (Update Request Select) in the R16\_TIMx\_CTLR1 register has been set to 1, setting UG location 1 will generate the update event UEV, but will not set the UIF flag to 1 (So no interrupt requests will be sent). This way, if the counter is cleared to zero when a capture event occurs, no update interrupt and no capture interrupt will be generated at the same time.

When an update event occurs, all registers will be updated and the update flag (UIF bit in the R16\_TIMx\_INTFR register) will be set to 1 (Depending on the URS bit):

- 1) The auto-reload shadow register will be updated with the preload value (R16\_TIMx\_ATRLR)
- 2) The prescaler buffer will be reloaded with the preload value (Contents of the R16\_TIMx\_PSC register)

### 13.3.2 Input Capture Mode

The input capture mode is one of the basic functions of the timer. The principle of input capture mode is that when a determined edge on the ICxPS signal is detected, a capture event is generated and the current value of the counter is latched into the compare capture register (R16\_TIMx\_CHCTLRx). The CCxIF (in R16\_TIMx\_INTFR) is set when a capture event occurs, and the corresponding interrupt is generated if enabled. If the CCxIF is already set when a capture event occurs, the CCxOF bit is set. The CCxIF can be cleared by software, or by hardware by reading the compare capture register. CCxOF is cleared by software.

An example of channel 1 to illustrate the steps to use the input capture mode is as follows.

- 1) Configure the CCxS domain to select the source of the ICx signal. For example, set it to 10b and select TI1FP1 as the source of IC1, not using the default setting, the CCxS domain defaults to making the comparison capture module the output channel.
- 2) Configure the ICxF domain to set the digital filter for the TI signal. The digital filter will sample the signal at a determined frequency, a determined number of times, and then output a hop. This sampling frequency and number of times is determined by ICxF.
- 3) Configure the CCxP bit to set the polarity of the TIxFPx. For example, keeping the CC1P bit low and selecting rising edge jumps.
- 4) Configure the ICxPS domain to set the ICx signal to be the crossover factor between ICxPS. For example, keeping ICxPS at 00b, without crossover.

- 5) Configure the CCxE bit to allow capturing the value of the core counter (CNT) into the compare capture register. Set the CC1E bit.
- 6) Configure the CCxIE bit as needed to determine whether to allow enable interrupts.

This completes the comparison capture channel configuration.

When a captured pulse is input to TI1, the value of the core counter (CNT) is recorded in the compare capture register, CC1IF is set, and the CCIOF bit is set when CC1IF has been set before. If the CC1IE bit is set, then an interrupt is generated. An input capture event can be generated by software by way of writing the event generation register (R16\_TIMx\_SWEVGR).

### 13.3.3 Compare Output Mode

The compare output mode is one of the basic functions of the timer. The principle of the compare output mode is to output a specific change or waveform when the value of the core counter (CNT) agrees with the value of the compare capture register. the OCxM field (in R16\_TIMx\_CHCTLRx) and the CCxP bit (in R16\_TIMx\_CCER) determine whether the output is a definite high or low level or a level flip. The CCxIF bit is also set when a compare coherent event is generated. If the CCxIE bit is pre-set, an interrupt will be generated.

To configure to compare output modes, proceed as follows.

- 1) Configure the clock source and auto-reload value of the core counter (CNT).
- 2) Set the count value to be compared to the comparison capture register (R16\_TIMx\_CHxCVR).
- 3) Set the CCxIE bit if an interrupt needs to be generated.
- 4) Keep OCxPE at 0 to disable the preload register for the compare capture register.
- 5) Setting the output mode, setting the OCxM field and the CCxP bit.
- 6) Enable the output, setting the CCxE bit.
- 7) Set the CEN bit to start the timer.

### 13.3.4 Forced Output Mode

The output pattern of the timer's compare capture channel can be forced by software to output a determined level without relying on comparison of the compare capture register's shadow register with the core counter.

This is done by setting OCxM to 100b, which forces OCxREF to low, or by setting OCxM to 101b, which forces OCxREF to high.

Note that by forcing OCxM to 100b or 101b, the comparison process between the internal main counter and the compare capture register is still going on, the corresponding flags are still set, and interrupt requests are still being generated.

### 13.3.5 PWM Input Mode

The PWM input mode is used to measure the duty cycle and frequency of PWM and is a special case of the input capture mode. The operation is the same as input capture mode except for the following differences: PWM occupies two compare capture channels and the input polarity of the two channels is set to opposite, one of the signals is set as trigger input and SMS is set to reset mode.

For example, to measure the period and frequency of the PWM wave input from TI1, the following operations are required.

- 1) Set TI1 (TI1FP1) to be the input of IC1 signal. Set CC1S to 01b.
- 2) Set TI1FP1 to rising edge active. Holding CC1P at 0.
- 3) Set TI1 (TI1FP2) as the input of IC2 signal. Set CC2S to 10b.
- 4) Select TI1FP2 to set to falling edge active. Set CC2P to 1.

- 5) Select TI1FP1 as the source of the clock source. set TS to 101b.
- 6) Set the SMS to reset mode, i.e. 100b.
- 7) Enables input capture. CC1E and CC2E are set.

### 13.3.6 PWM Output Mode

PWM output mode is one of the basic functions of the timer. PWM output mode is most commonly used to determine the PWM frequency using the reload value and the duty cycle using the capture comparison register. Set 110b or 111b in the OCxM field to use PWM mode 1 or mode 2, set the OCxPE bit to enable the preload register, and finally set the ARPE bit to enable the automatic reload of the preload register. The value of the preload register can only be sent to the shadow register when an update event occurs, so the UG bit needs to be set to initialize all registers before the core counter starts counting.

### 13.3.7 Single Pulse Mode

The single pulse mode can respond to a specific event by generating a pulse after a delay, with programmable delay and pulse width. Setting the OPM bit stops the core counter when the next update event UEV is generated (Counter flips to 0).

Figure 13-4 Event generation and impulse response

As shown in Figure 13-4, a positive pulse of length  $T_{pulse}$  needs to be generated on OC1 after a delay  $T_{delay}$  at the beginning of a rising edge detected on the TI2 input pin.

- 1) Set TI2 to trigger. Setting the CC2S field to 01b to map TI2FP2 to TI2; setting the CC2P bit to 0b to set TI2FP2 as rising edge detection; setting the TS field to 110b to set TI2FP2 as trigger source; setting the SMS field to 110b to set TI2FP2 to be used to start the counter.
- 2)  $T_{delay}$  is defined by the Compare Capture Register and  $T_{pulse}$  is determined by the value of the Auto Reload Value Register and the Compare Capture Register.

### 13.3.8 Synchronization of TIMx Timers and External Triggers

The timer can be synchronized with an external trigger in reset mode, gated mode and trigger mode.

#### Slave mode: reset mode

The counter and its prescaler can be reinitialized in response to a trigger input event; if the URS bit of the

R16\_TIMx\_CTLR1 register is low, an update event UEV is generated; all preload registers (R16\_TIMx\_ATRLR, R16\_TIMx\_CHxCVR) are then updated.

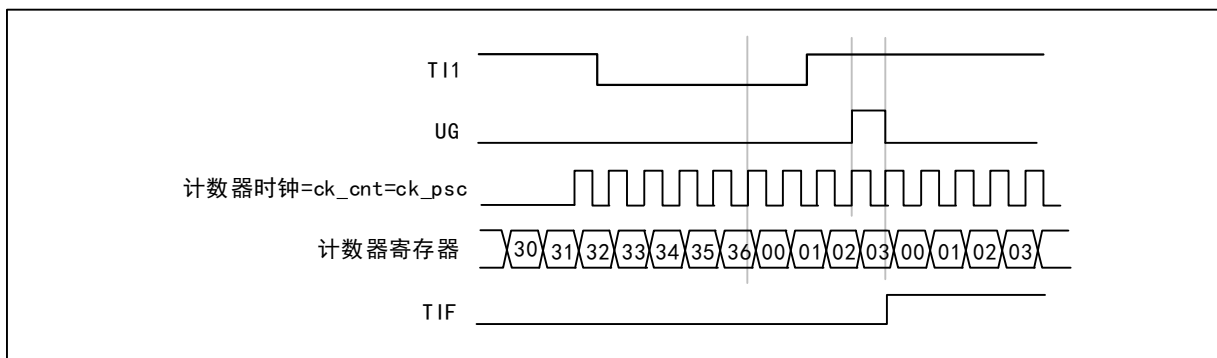

In the following example, the up counter is cleared to zero when a rising edge occurs on the TII input:

- 1) Configure channel 1 to detect the rising edge of TII. Configure the input filter bandwidth (This example does not require any filter, so keep IC1F = 0000). There is no need to configure the capture divider as it is not used for trigger operation. the CC1S bit selects only the input capture source, i.e. CC1S=01 (in R16\_TIMx\_CCMR1). Write CC1P=0 and CC1NP='0' to the R16\_TIMx\_CCER register to verify polarity (rising edge detection only).
- 2) Write SMS=100 to R16\_TIMx\_SMCFGR to configure the timer to reset mode; write TS=101 to R16\_TIMx\_SMCFGR to select TII as input source.
- 3) Write CEN=1 to R16\_TIMx\_CTLR1 to start the counter.

The counter counts using the internal clock and then runs normally, when there is a TII rising edge the counter clears and starts counting again from 0. At the same time, the trigger flag TIF position 1, after enabling interrupt, allows an interrupt request to be sent. (Depends on the TIE (Interrupt Enable) bit in the R16\_TIMx\_DMAINTENR register).

The diagram below shows the action when the auto-reload register R16\_TIMx\_ARR = 0x36. The delay between the rising edge of TII and the actual counter reset is caused by the resynchronization circuitry at the TII input.

Figure 13-5 Control circuit in reset mode

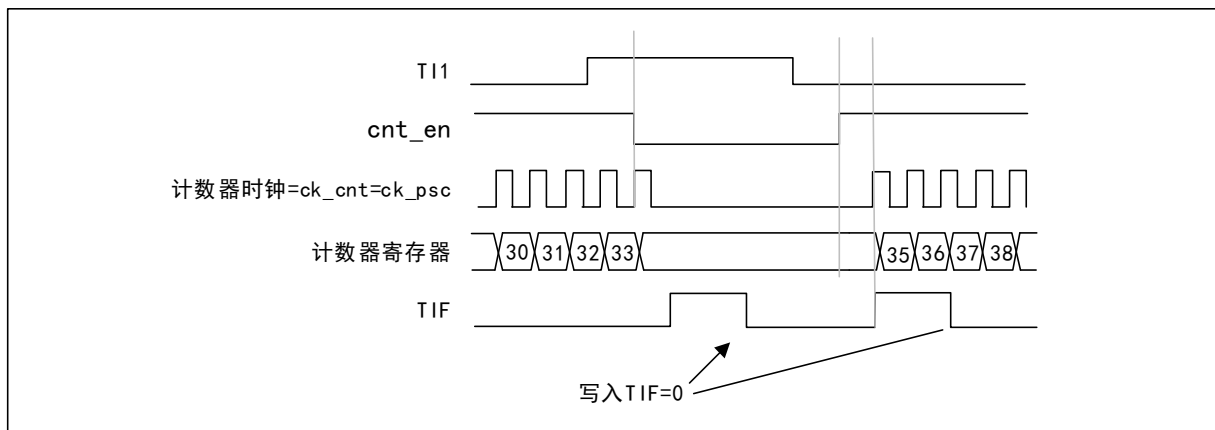

### Slave mode: Gated mode

The level of the input signal enables the counter. In the following example, the counter counts up only when TII is low:

- 1) Configure channel 1 to detect a low level on TII. Configure the input filter bandwidth (This example does not require any filter, so keep IC1F = 0000). There is no need to configure the capture divider as it is not used for trigger operation. the CC1S bit selects only the input capture source, i.e. CC1S=01 (In R16\_TIMx\_CCMR1). Write CC1P=1 and CC1NP='0' to the R16\_TIMx\_CCER register to verify polarity (detect low level only).
- 2) Write SMS=101 to R16\_TIMx\_SMCFGR to configure the timer for gated mode; write TS=101 to R16\_TIMx\_SMCFGR to select TII as input source.
- 3) Write CEN=1 to R16\_TIMx\_CTLR1 to start the counter. In gated mode, if CEN=0, the counter will not start regardless of the trigger input level.

As long as TII is low, the counter starts counting based on the internal clock and stops counting when TII goes high. When the counter starts or stops it sets TIF position 1 in R16\_TIMx\_INTFR. The delay between the rising edge of TII and the actual counter reset is caused by the resynchronization circuitry at the TII input.

Figure 13-6 Control circuit in gated mode

**Slave mode: trigger mode**

An event on the selected input will enable the counter. In the following example, the up counter is activated when a rising edge occurs on the TI2 input:

- 1) Configure channel 2 to detect the rising edge of TI2. Configure the input filter bandwidth (This example does not require any filter, so keep IC2F = 0000). There is no need to configure the capture divider as it is not used for trigger operation. the CC2S bit selects only the input capture source by setting CC2S=01 (in R16\_TIMx\_CCMR1). Write CC2P=1 and CC2NP='0' to the R16\_TIMx\_CCER register to verify polarity (Detect low level only)
- 2) Write SMS=110 to R16\_TIMx\_SMCFGR register to configure the timer to trigger mode; write TS=110 to R16\_TIMx\_SMCFGR register to select TI2 as input source.

When there is a rising edge of TI2, the counter starts counting driven by the internal clock, while TIF is set to 1. The delay between the rising edge of TI2 and the actual counter start is caused by the resynchronization circuitry at the TI2 input.

Figure 13-7 Control circuit in trigger mode

**13.3.9 Debug mode**

When the system enters the debug mode, the timer can be controlled to continue running or stop according to the setting of DBG module.

## 13.4 Register Description

Table 13-1 TIM3-related registers list

| Name               | Access address | Description                            | Reset value |
|--------------------|----------------|----------------------------------------|-------------|

### 13.4.6 Compare/Capture Control Register 1 (TIM3\_CHCTLR1)

Offset address: 0x18

The channel can be used in input (capture mode) or output (compare mode), and the direction of the channel is defined by the corresponding CCxS bit. The other bits of this register serve different purposes in input and output modes. OCxx describes the function of the channel in output mode and ICxx describes the function of the channel in input mode.

# Chapter 14 Universal Synchronous Asynchronous Receiver Transmitter (USART)

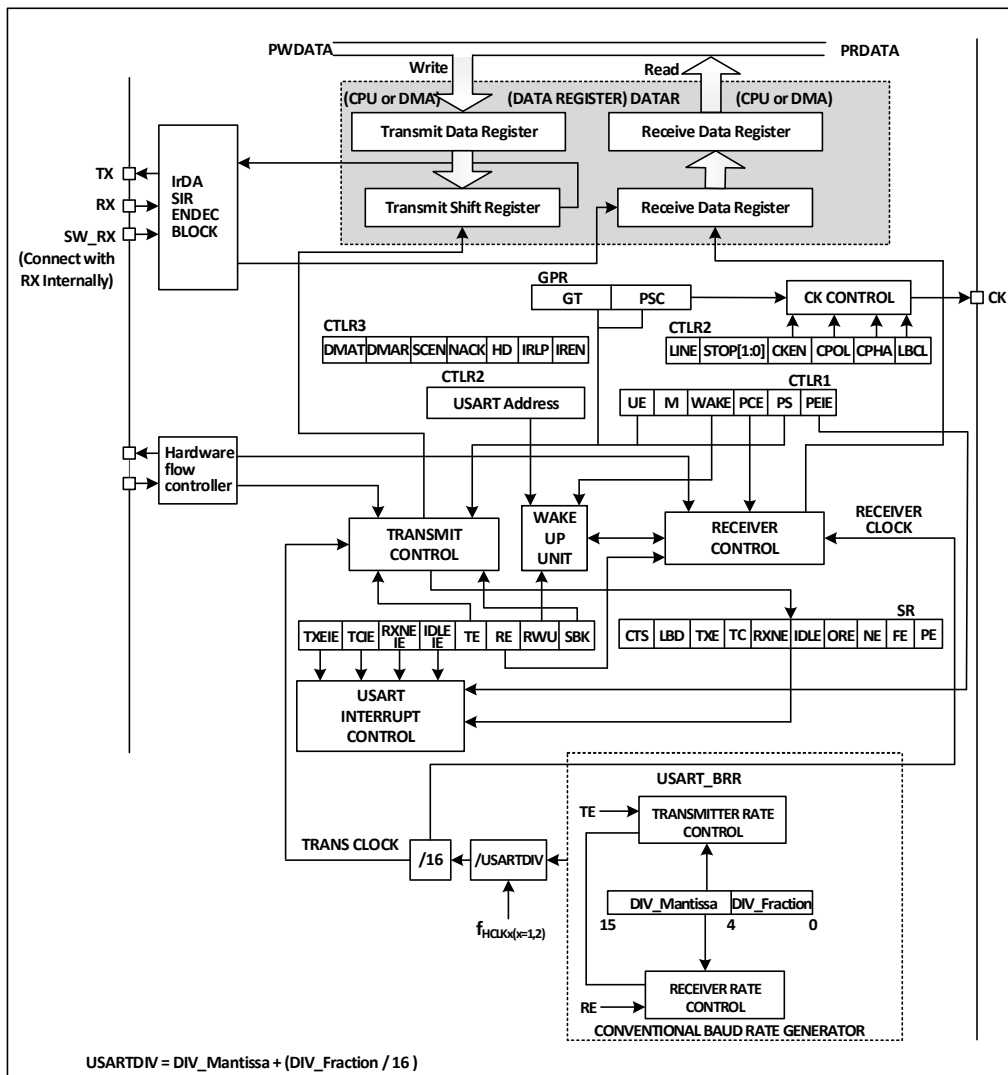

The module contains 4 Universal Synchronous Asynchronous Transceiver (USART1/2/3/4).

## 14.1 Main Features

- Full-duplex or half-duplex synchronous or asynchronous communication
- NRZ data format
- Fractional baud rate generator, up to 3Mbps
- Programmable data length
- Configurable stop bits
- Support LIN, IrDA encoders, smart cards
- DMA support
- Multiple interrupt sources

## 14.2 Overview

Figure 14-1 Block diagram of a general-purpose synchronous/asynchronous transceiver

When TE (Transmit enable bit) is set, the data in the transmit shift register is output on the TX pin and the clock is output on the CK pin. When transmitting, the first bit shifted out is the least significant bit and each data frame starts with a low start bit, then the transmitter sends an 8- or 9-bit data word depending on the setting on the M (Word length) bit, and finally a configurable number of stop bits. If equipped with a parity check bit, the last bit of the data word is the check bit. After the TE is set an idle frame is sent, which is 10 or 11 bits high and contains the stop bit. The disconnect frame is 10 or 11 bits low followed by the stop bit.

## 14.3 Baud Rate Generator

The baud rate of the transceiver =  $HCLK / (16 * USARTDIV)$ , HCLK is the clock of HB. The value of USARTDIV is determined by the two fields DIV\_M and DIV\_F in USART\_BRR, which is calculated by the formula The formula is as follows.

$$USARTDIV = DIV\_M + (DIV\_F / 16)$$

It is important to note that the bit rate generated by the baud rate generator may not always generate exactly the baud rate required by the user, and there may be deviations. In addition to taking as close a value as possible, a way

to reduce the deviation is to increase the HB clock. For example, if you set the baud rate to 115200bps, the value of USARTDIV is set to 39.0625, which will give you a baud rate of exactly 115200bps at the highest frequency, but if you need a baud rate of 921600bps, the calculated USARTDIV is 4.88, but the closest value filled in USART\_BRR is actually only 4.875. 4.875, the actual baud rate is 923076bps, which is 0.16% error.

When the serial waveform sent by the sender is transmitted to the receiver, the baud rate of the receiver and the sender is subject to some error. The error mainly comes from three aspects: the actual baud rate of the receiver and the sender is not the same; the receiver and the sender's clock has errors; the waveform in the line generated by the change. Peripheral module receiver is a certain receiving tolerance, when the sum of the above three aspects of the total deviation is less than the module's tolerance limit, the total deviation does not affect the transmission and reception. The tolerance limit of the module is affected by whether to use fractional baud rate and M-bit (Data field word length), using fractional baud rate and using 9-bit data field length will reduce the tolerance limit, but not less than 3%.

## 14.4 Synchronous Mode

Synchronous mode allows the system to output a clock signal when using the USART module. When synchronous mode is enabled to send data externally, the CK pin will output the clock externally at the same time.

The way to turn on the synchronous mode is to the CLKEN position bit in control register 2 (R16\_USARTx\_CTLR2), but also need to turn off the LIN mode, smart card mode, infrared mode and half duplex mode, i.e. ensure that the SCEN, HDSEL and IREN bits are in reset, these three in control register 3 (R16\_USARTx\_CTLR3).

The key point of using synchronous mode is the clock output control. There are several points to note.

The USART module synchronization mode works only in the main mode, i.e. the CK pin outputs only the clock and does not receive inputs.

Outputs a clock signal only when data is output on the TX pin.

The LBCL bit determines whether the clock is output when the last data bit is sent, the CPOL bit determines the polarity of the clock, and the CPHA determines the phase of the clock. These three bits are in control register 2 (R16\_USARTx\_CTLR2), which needs to be set when TE and RE are not enabled, see Figure 14-2 for the differences. The receiver will only sample at the output clock in synchronous mode, requiring a certain amount of signal build time and hold time from the device, as shown in Figure 14-3.

Figure 14-2 USART clock timing example (M=0)

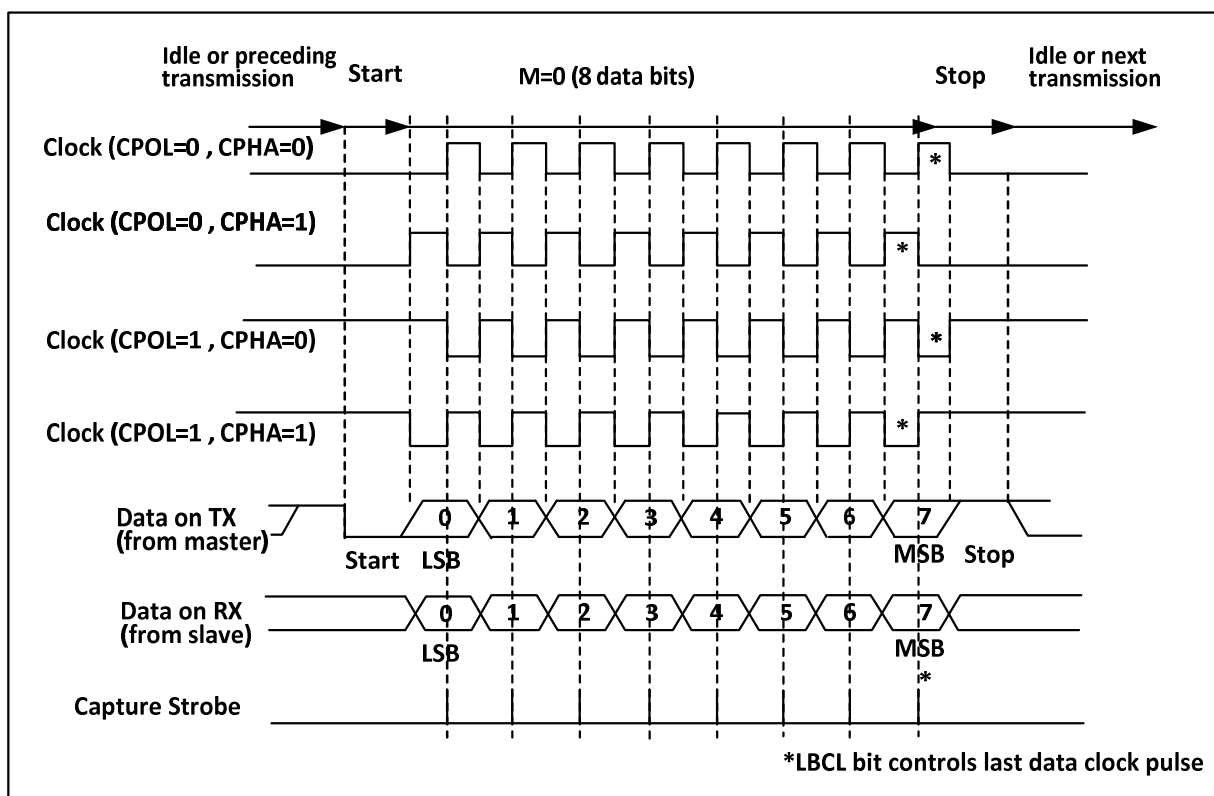

Figure 14-3 Data sample hold time

### 14.5 1-Wire Half-Duplex Mode

Half-duplex mode supports the use of a single pin (TX pin only) for receive and transmit, with the TX and RX pins connected internally on the chip.

The way to turn on the half-duplex mode is to set the HDSEL position bit in control register 3 (R16\_USARTx\_CTLR3), but it is also necessary to turn off the LIN mode, smart card mode, IR mode and synchronous mode, i.e. to ensure that the SCEN, CLKEN and IREN bits are in reset, which are in control registers 2 and 3 (R16\_USARTx\_CTLR2 and R16\_USARTx\_CTLR3).

After setting to half duplex mode, you need to set the IO port of the TX to output mode plus pull. With TE set, data will be sent out as soon as it is written to the data register. In particular, note that half-duplex mode may cause bus conflicts when multiple devices use a single bus to send and receive, which needs to be avoided by the user with

the software itself.

## 14.6 Smart Card

Smart card mode supports ISO7816-3 protocol access to smart card controllers.

The smart card mode is turned on by setting the SCEN position bit in control register 3 (R16\_USARTx\_CTLR3), but it is also necessary to turn off LIN mode, half duplex mode and IR mode, i.e. to ensure that the LINEN, HDSEL and IREN bits are in reset, but CLKEN can be turned on to output the clock, these bits are in control registers 2 and 3 (R16\_USARTx\_CTLR2 and R16\_USARTx\_CTLR3).

To support smart card mode, USART should be set to 8 bits of data plus 1 bit of parity, and its stop bit is recommended to be configured to 1.5 bits for both transmit and receive. Smart card mode is a single-wire half-duplex protocol that uses the TX line for data communication and should be configured as output pull-up. When the receiver receives a frame of data and detects a parity error, it sends a NACK signal, i.e., it actively pulls the TX down by one cycle during the stop bit, and the sender detects the NACK signal, which generates a frame error whereby the application can retransmit. Figure 14-4 shows the waveforms on the TX pin in the correct case and in the case of a parity error. the TC flag (Transmit complete flag) of the USART can delay the GT (Protection time) generation by one clock, and the receiver will not recognize the NACK signal it sets as the start bit.

Figure 14-4 (Un)Occurrence of parity error diagram

In smart card mode, the waveform output from the CK pin when enabled has nothing to do with communication; it simply clocks the smart card with the value of the HB clock followed by a five-bit settable clock division (Twice the value of the PSC, up to 62 divisions).

## 14.7 IrDA

The USART module supports control of IrDA infrared transceivers for physical layer communication. The LINEN, STOP, CLKEN, SCEN and HDSEL bits must be cleared to use IrDA. NRZ (Non-return to zero) coding is used between the USART module and the SIR physical layer (Infrared transceiver) and is supported up to 115200 bps rates.

IrDA is a half-duplex protocol, if UASRT is sending data to SIR physical layer, then IrDA decoder will ignore the newly sent IR signal, if USART is receiving data from SIR, then SIR will not accept the signal from USART. the level logic of USART to SIR and SIR to USART is different. In SIR receive logic, the high level is 1 and the low level is 0, but in SIR send logic, the high level is 0 and the low level is 1.

## 14.8 DMA

The USART module supports DMA function, which can be used to achieve fast and continuous transmitting and receiving. When DMA is enabled, the DMA writes data from the set memory space to the transmit buffer when TXE is set. When using DMA to receive, each time RXNE is set, DMA transfers the data in the receive buffer to a specific memory space.

## 14.9 Interrupts

USART module supports a variety of interrupt sources, including transmit data register empty (TXE), CTS, transmit complete (TC), receive data ready (TXNE), data overflow (ORE), line idle (IDLE), parity error (PE), disconnect flag (LBD), noise (NE), overflow for multi-buffered communication (ORT), and frame error (FE), among others.

Table 14-1 Relationship between interrupts and corresponding enable bits

| Interrupt source                                 | Enable bit |
|--------------------------------------------------|------------|
| Transmit data register empty (TXE)               | TXEIE      |
| Allowed to transmit (CTS)                        | CTSIE      |
| Transmission complete (TC)                       | TCIE       |
| Received data ready to be read (TXNE)            | TXNEIE     |
| Overrun error detected (ORE)                     |            |
| Idle line detected (IDLE)                        | IDLEIE     |
| Parity error (PE)                                | PEIE       |
| Break flag (LBD)                                 | LBDIE      |
| Noise flag (NE)                                  | EIE        |
| Overflow of multi-buffered communication (ORT)   |            |
| Frame error (FE) for multibuffered communication |            |

## 14.10 Register Description

Table 14-2 USART1-related registers list

| Name             | Access address | Description                                    | Reset value |

### 14.10.1 USART Status Register (USARTx\_STATR) (x=1/2/3/4)

Offset address: 0x00

| Bit     | Name     | Access | Description                                             | Reset value |
|---------|----------|--------|---------------------------------------------------------|-------------|
| [31:10] | Reserved | RO     | Reserved                                                | 0           |
| 9       | CTS      | RW0    | CTS state change flag. If the CTSE bit is set, this bit | 0           |

|   |      |     |                                                                                                                                                                                                                                                                                                                                                                                                                                |   |
|---|------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
|   |      |     | <p>will be set high by hardware when the nCTS output state changes. It is cleared to zero by software. If the CTSIE bit is already set, an interrupt will be generated.</p> <p>1: The presence of changes on the nCTS state line.<br/>0: No change on the nCTS state line.</p>                                                                                                                                                 |   |
| 8 | LBD  | RW0 | <p>LIN disconnect detection flag. This bit is set by hardware when a LIN disconnect is detected. It is cleared by software.</p> <p>If LBDIE is already set, an interrupt will be generated.</p> <p>1: LIN disconnection detected.<br/>0: No detection of pending LIN disconnection.</p>                                                                                                                                        | 0 |
| 7 | TXE  | RO  | <p>Transmit data register empty flag. This bit is set by hardware when the data in the TDR register is transferred to the shift register by hardware. If TXEIE is already set, an interrupt will be generated to perform a write operation to the data register and this bit will be reset.</p> <p>1: The data has been transferred to the shift register.<br/>0: The data has not been transferred to the shift register.</p> | 1 |
| 6 | TC   | RW0 | <p>Transmit completion flag. When a frame containing data is sent and TXE is set, the hardware will set this bit, and if TCIE is set, an interrupt will be generated, and the software will clear this bit by reading it and then writing to the data register. It is also possible to write 0 directly to clear this bit.</p> <p>1: Transmitting completed.<br/>0: Transmitting is not yet complete.</p>                      | 1 |
| 5 | RXNE | RW0 | <p>Read data register non-empty flag, this bit is set by hardware when data in the shift register is transferred to the data register. If RXNEIE is already set, a corresponding interrupt is also generated. A read operation of the data register clears this bit. It is also possible to clear the bit by writing a 0 directly.</p> <p>1: Data received and able to be read out.<br/>0: The data has not been received.</p> | 0 |
| 4 | IDLE | RO  | <p>Bus idle flag. When the bus is idle, this bit will be set by hardware. If IDLEIE is already set, the corresponding interrupt will be generated. The operation of reading the status register and then reading the data register will clear this bit.</p> <p>1: The bus is idle.<br/>0: No bus idle is detected.</p>                                                                                                         | 0 |

|   |     |    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |   |
|---|-----|----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
|   |     |    | <i>Note: This bit will not be set again until RXNE is set.</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |   |
| 3 | ORE | RO | <p>Overload error flag. This bit will be set when there is data in the receive shift register that needs to be transferred to the data register, but there is still data in the receive field of the data register that has not been read out. If RXNEIE is set, the corresponding interrupt will also be generated.</p> <p>1: Occurrence of an overload error.<br/>0: No overload error.</p> <p><i>Note: In case of an overload error, the value of the data register is not lost, but the value of the shift register is overwritten. If the EIE able bit is set, the ORE flag position bit generates an interrupt in multi-buffer communication mode.</i></p> | 0 |
| 2 | NE  | RO | <p>Noise error flag. It is set by hardware when the noise error flag is detected. The operation of reading the status register and then reading the data register resets this bit.</p> <p>1: Noise detected.<br/>0: No noise is detected.</p> <p><i>Note: This bit does not generate an interrupt. If the EIE bit is set, the FE flag position bit generates an interrupt in multi-buffer communication mode.</i></p>                                                                                                                                                                                                                                            | 0 |
| 1 | FE  | RO | <p>Frame error flag. This bit will be set by hardware when a synchronization error, excessive noise or disconnect character is detected. Reading this bit and then reading the data register operation will reset this bit.</p> <p>1: Frame error detected.<br/>0: No frame error detected.</p> <p><i>Note: This bit will not generate an interrupt. If the EIE bit is set, the FE flag position bit will generate an interrupt in multi-buffer communication mode.</i></p>                                                                                                                                                                                      | 0 |
| 0 | PE  | RO | <p>Checksum error flag. In receive mode, hardware sets this bit if a parity check error is generated. A read of this bit and then a read of the data register operation resets this bit. Before clearing this bit, software must wait for the RXNE flag bit to be set. If the PEIE has been set previously, then this bit being set generates a corresponding interrupt.</p> <p>1: A parity error.<br/>0: No inspection error.</p>                                                                                                                                                                                                                               | 0 |

| 11 | WAKE   | RW | Wake-up bit. This bit determines the method of waking up the USART.<br>1: Address marker; 0: Bus idle.                                                                                                                                                                                                                                                                                                                                                | 0 |
| 10 | PCE    | RW | The parity bit is enabled. For the receiver, it is the parity check of the data; for the sender, it is the insertion of the parity bit. Once this bit is set, the parity bit enable will take effect only after the current byte transmission is completed.                                                                                                                                                                                           | 0 |
| 9  | PS     | RW | Parity selection. 0 means even parity, 1 means odd parity. When this bit is set, the parity bit enable will take effect only after the current byte transmission is completed.                                                                                                                                                                                                                                                                        | 0 |
| 8  | PEIE   | RW | Parity check interrupt enable bit. This bit indicates that parity check error interrupts are allowed.                                                                                                                                                                                                                                                                                                                                                 | 0 |
| 7  | TXEIE  | RW | TXE interrupt enable. This bit indicates that a TXE interrupt is allowed to be generated.                                                                                                                                                                                                                                                                                                                                                             | 0 |
| 6  | TCIE   | RW | Transmit completion interrupt enable. This bit indicates that the transmit completion interrupt is allowed to be generated.                                                                                                                                                                                                                                                                                                                           | 0 |
| 5  | RXNEIE | RW | RXNE interrupt enable. This bit indicates that a RXNE interrupt is allowed to be generated.                                                                                                                                                                                                                                                                                                                                                           | 0 |
| 4  | IDLEIE | RW | IDLE interrupt enable. This bit allows IDLE interrupt to be generated.                                                                                                                                                                                                                                                                                                                                                                                | 0 |
| 3  | TE     | RW | Transmit enable. Setting this bit will enable the transmitter.                                                                                                                                                                                                                                                                                                                                                                                        | 0 |
| 2  | RE     | RW | Receive enable. Setting this bit enables the receiver, which starts detecting the start bit on the RX pin.                                                                                                                                                                                                                                                                                                                                            | 0 |
| 1  | RWU    | RW | Receiver wakeup. This bit determines whether to place the USART in silent mode.<br>1: The receiver is in silent mode.<br>0: The receiver is in normal operation mode.<br><i>Note 1: Before setting the RWU bit, the USART needs to receive a data byte first, otherwise it cannot be woken up by bus idle in silent mode.</i><br><i>Note 2: When configured as address mark wake-up, the RWU bit cannot be modified by software when RXNE is set.</i> | 0 |
| 0  | SBK    | RW | Send break bit.<br>Set this bit to send break character. It is reset by hardware on the stop bit of the break frame.<br>1: Send; 0: Do not send.                                                                                                                                                                                                                                                                                                      | 0 |

### 14.10.5 USART Control Register 2 (USARTx\_CTLR2) (x=1/2/3/4)

Offset address: 0x10

| Bit     | Name      | Access | Description                                                                                                                                                                                                                                                                                                                                                                                              | Reset value |
|---------|-----------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [31:15] | Reserved  | RO     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                 | 0           |
| 14      | LINEN     | RW     | The LIN mode enable bit, set to enable LIN mode. In LIN mode, the SBK bit can be used to send LIN sync break symbols and to detect LIN sync break characters.                                                                                                                                                                                                                                            | 0           |
| [13:12] | STOP[1:0] | RW     | STOP bits.<br>These two bits are used for programming the stop bits.<br>00: 1 Stop bit<br>01: 0.5 Stop bit<br>10: 2 Stop bits<br>11: 1.5 Stop bit                                                                                                                                                                                                                                                        | 0           |
| 11      | CLKEN     | RW     | Clock enable.<br>This bit allows the user to enable the CK pin.<br>1: Enable<br>0: Disable                                                                                                                                                                                                                                                                                                               | 0           |
| 10      | CPOL      | RW     | Clock polarity setting bit. In synchronous mode, this bit can be used to select the polarity of the clock output on the SLCK pin, and in conjunction with CPHA to generate the desired clock/data sampling relationship.<br>1: Hold high on the CK pin when the bus is idle;<br>0: Hold low on the CK pin when the bus is idle.<br><i>Note: This bit cannot be modified after enabling the transmit.</i> | 0           |
| 9       | CPHA      | RW     | Clock phase setting bit. In synchronous mode, this bit can be used to select the phase of the clock output on the SLCK pin, and in conjunction with the CPOL bit to produce the desired clock/data sampling relationship.<br>1: Data capture at the second edge of the clock;<br>0: Data capture at the first edge of the clock.<br><i>Note: This bit cannot be modified when transmit is enabled.</i>   | 0           |

|       |          |    |                                                                                                                                                                                                                                                                                                                                                                                            |   |
|-------|----------|----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
| 8     | LBCL     | RW | Last clock pulse control bit.<br>In synchronous mode, use this bit to control whether the clock pulse corresponding to that last data byte sent is output on the CK pin;<br>1: The clock pulse for the last bit of data is not output from CK;<br>0: The clock pulse for the last bit of data will be output from CK.<br><i>Note: This bit cannot be modified after enabling transmit.</i> | 0 |
| 7     | Reserved | RW | Reserved                                                                                                                                                                                                                                                                                                                                                                                   | 0 |
| 6     | LBDIE    | RW | LIN Break detection interrupt enable, this position bit enables interrupts caused by LBD.                                                                                                                                                                                                                                                                                                  | 0 |
| 5     | LBDL     | RW | LIN Break detection length, this bit is used to select whether the disconnect detection is 11 bits or 10 bits.<br>1: 11-bit disconnect detection.<br>0: 10-bit disconnect detection.                                                                                                                                                                                                       | 0 |
| 4     | Reserved | RW | Reserved                                                                                                                                                                                                                                                                                                                                                                                   | 0 |
| [3:0] | ADD[3:0] | RW | Address field to set the USART node address of this device. Used in silent mode under multi-processor communication to wake up a USART device using the address token.                                                                                                                                                                                                                     | 0 |

**14.10.6 USART Control Register 3 (USARTx\_CTLR3) (x=1/2/3/4)**

Offset address: 0x14

| Bit     | Name     | Access | Description                                                                               | Reset value |
|---------|----------|--------|-------------------------------------------------------------------------------------------|-------------|
| [31:11] | Reserved | RO     | Reserved.                                                                                 | 0           |
| 10      | CTSIE    | RW     | CTSIE interrupt enable bit, when set this bit will generate an interrupt when CTS is set. | 0           |
| 9       | CTSE     | RW     | CTS enable bit, setting this bit will enable CTS flow control.                            | 0           |
| 8       | RTSE     | RW     | RTS enable bit, setting this bit will enable RTS flow control.                            | 0           |
| 7       | DMAT     | RW     | DMA transmit enable bit. This position 1 uses DMA when transmitting.                      | 0           |
| 6       | DMAR     | RW     | DMA receive enable bit. This position 1 uses                                              | 0           |

|   |       |    |                                                                                                                        |   |
|---|-------|----|------------------------------------------------------------------------------------------------------------------------|---|
|   |       |    | DMA when receiving.                                                                                                    |   |

## Chapter 15 Inter-integrated Circuit (I2C) interface

The internal integrated circuit bus (I2C or IIC) is widely used for communication between microcontrollers and sensors and other off-chip modules. It inherently supports multi-master and multi-slave modes and can communicate at 100KHz (Standard) and 400KHz (Fast) using just 2 wires (SDA and SCL).

### 15.1 Main Features

- Support Master and Slave modes, support multiple masters and slave.
- Support two speed modes: 100KHz and 400KHz, compatible with the I2C 2-wire serial bus specification.
- Support 7-bit or 10-bit addresses.
- Slave devices support dual 7-bit addresses.
- Support bus broadcast.
- Support PEC.
- Support bus arbitration, error detection, PEC checksum, extended clock.

### 15.2 Overview

I2C is a half-duplex bus that can only operate in one of the following four modes at the same time: master device transmit mode, master device receive mode, slave device transmit mode and slave device receive mode. the I2C module works in slave mode by default and automatically switches to master mode when a start condition is generated and to slave mode when arbitration is lost or a stop signal is generated. the I2C module supports multi-master functionality. When working in master mode, the I2C module actively emits data and addresses. Both data and address are transmitted in 8-bit units, with the high bit before and the low bit after. After the start event is a one-byte (In 7-bit address mode) or two-byte (In 10-bit address mode) address, and for every 8-bit data or address sent by the host, the slave needs to reply with an answer ACK, which pulls the SDA bus low, as shown in Figure 13-1.

Figure 15-1 I2C Timing Diagram

### 15.3 Master Mode

In master mode, the I2C module dominates the data transfer and outputs the clock signal, and the data transfer starts with a start event and ends with an end event. The steps to use master mode communication are:

- 1) Setting the correct clock in control register 2 (R16\_I2C1\_CTLR2) and clock control register

(R16\_I2C1\_CKCFGR).

- 2) Setting the PE bit in the control register (R16\_I2C1\_CTLR1) to start the peripheral.
- 3) Set the START bit in the control register (R16\_I2C1\_CTLR1) to generate the start event.

After setting the START bit, the I2C module will automatically switch to the main mode, the MSL bit will be set and the start event will be generated. After the start event is generated, the SB bit will be set and if the ITEVTEN bit (In R16\_I2C1\_CTLR2) is set, an interrupt will be generated. The status register 1 (R16\_I2C1\_STAR1) should be read at this time and the SB bit will be cleared automatically after writing from the address to the data register.

- 4) If the 10-bit address mode is used, then the write data register sends the header sequence (The header sequence is 11110xx0b, where the xx bits are the top two bits of the 10-bit address).

After sending the header sequence, the ADD10 bit of the status register will be set, and if the ITEVTEN bit has been set, an interrupt will be generated, at this time the R16\_I2C1\_STAR1 register should be read and the ADD10 bit cleared after writing the second address byte to the data register.

Then write the data register to send the second address byte, after sending the second address byte, the ADDR bit of the status register will be set, if the ITEVTEN bit is already set, an interrupt will be generated, at this time the R16\_I2C1\_STAR1 register should be read and then read the R16\_I2C1\_STAR2 register once to clear the ADDR bit;

If the 7-bit address mode, then write data register to send address byte, after sending address byte, ADDR bit of status register will be set, if ITEVTEN bit has been set, then interrupt will be generated, at this time, R16\_I2C1\_STAR1 register should be read and then R16\_I2C1\_STAR2 register should be read once to clear ADDR bit;

In 7-bit address mode, the first byte sent is the address byte, the first 7 bits represent the address of the target slave device, the 8<sup>th</sup> bit determines the direction of the subsequent message, 0 means the master device writes data to the slave device, 1 means the master device reads information to the slave device.

In 10-bit address mode, as shown in Figure 13-3, in the send address phase, the first byte is 11110xx0, xx is the highest 2 bits of the 10-bit address, and the second byte is the lower 8 bits of the 10-bit address. If subsequently enter the master device transmit mode, continue to send data; if subsequently ready to enter the master device receive mode, you need to re-send a start condition, follow to send a byte as 11110xx1, and then enter the master device receive mode.

Figure 15-2 Schematic diagram of master sending and receiving data at 10-bit address

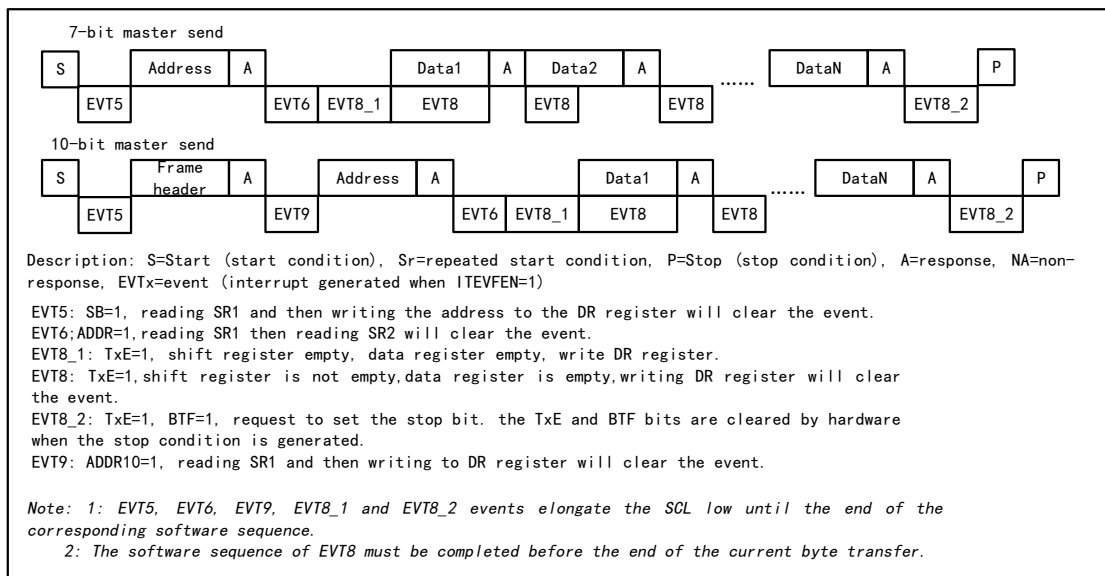

**Master transmit mode:**

The master device's internal shift register sends data from the data register to the SDA line. When the master device receives an ACK, TxE in status register 1 (R16\_I2C1\_STAR1) is set, and an interrupt is also generated if ITEVTEN and ITBUFEN are set. Writing data to the data register will clear the TxE bit.

If the TxE bit is set and no new data was written to the data register before the last data was sent, then the BTF bit will be set and SCL will remain low until it is cleared, and writing data to the data register after reading R16\_I2C1\_STAR1 will clear the BTF bit.

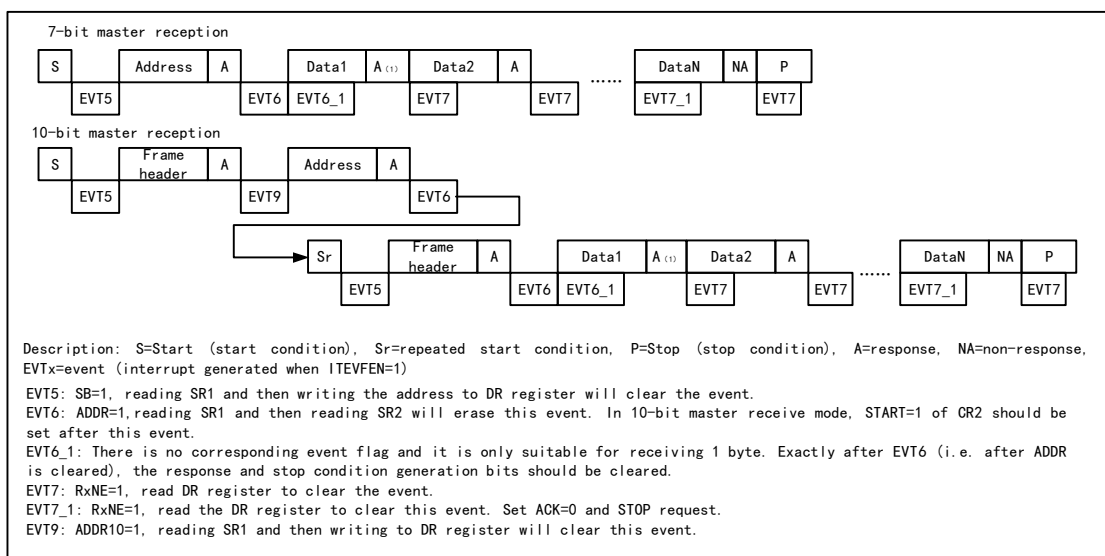

Figure 15-3 Master transmitter transmission sequence diagram

Master receive mode:

The I2C module will receive data from the SDA line and write it into the data register via a shift register. After each byte, if the ACK bit is set, then the I2C module will send an answer low, and the RxNE bit will be set, and an interrupt will be generated if ITEVTEN and ITBUFEN are set. If RxNE is set and the original data is not read before the new data is received, the BTF bit will be set and SCL will remain low until the BTF is cleared, and reading R16\_I2C1\_STAR1 and then reading the data register will clear the BTF bit.

Figure 15-4 Receiver transmission sequence diagram

The master device will actively send an end event, i.e. set the STOP bit, when it finishes sending data. In receive mode, the master device needs to NAK at the answer position of the last data bit. note that after generating NAK, the I2C module will switch to slave mode.

## 15.4 Slave Mode

When in slave mode, the I2C module recognizes its own address and the broadcast call address. The software can control whether the recognition of the broadcast call address is enabled or disabled. Once a start event is detected, the I2C module compares the SDA data through the shift register with its own address (Number of bits depends on ENDUAL and ADDMODE) or the broadcast address (When ENGC is set), if there is a mismatch it will be ignored until a new start event is generated. If it matches the header sequence, an ACK signal is generated and the address of the second byte is waited for; if the address of the second byte also matches or the full segment address matches in the case of a 7-bit address, then:

First an ACK answer is generated;

The ADDR bit is set, and if the ITEVTEN bit is already set, then a corresponding interrupt is also generated;

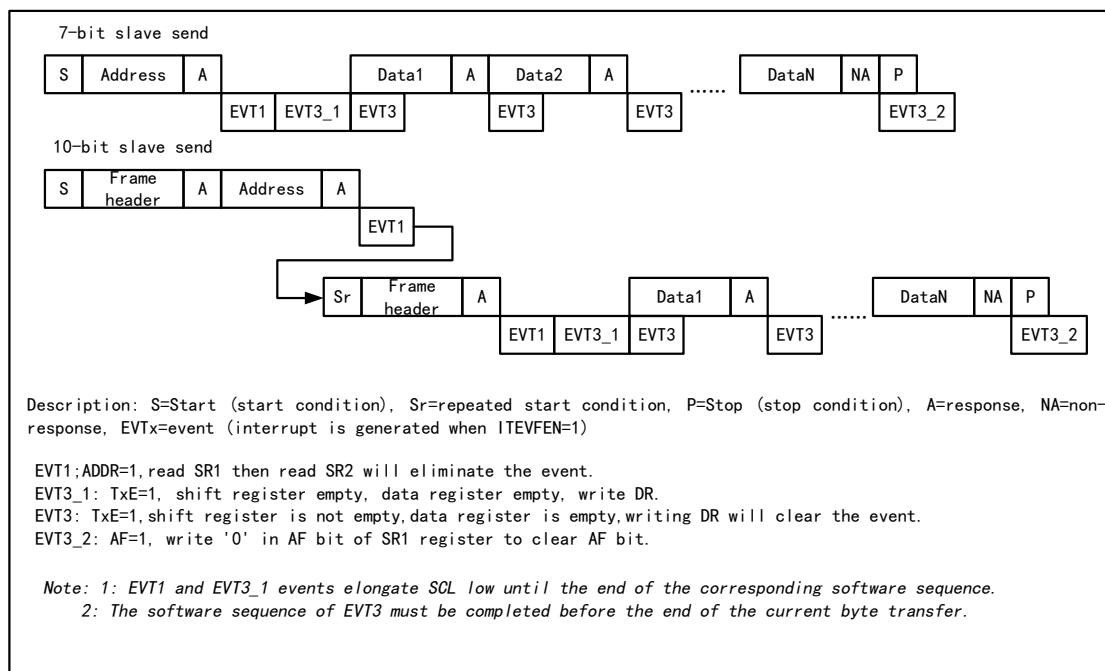

if the dual address mode is used (ENDUAL bit is set), the DUALF bit also needs to be read to determine which address the host is evoking.

The slave mode is receive mode by default. In case the last bit of the received header sequence is 1, or the last bit of the 7-bit address is 1 (Depending on whether the header sequence is received for the first time or a normal 7-bit address), the I2C module will go to transmitter mode and the TRA bit will indicate whether it is currently receiver or transmitter mode.

### Slave transmit mode:

After clearing the ADDR bit, the I2C module sends bytes from the data register to the SDA line via a shift register. After an answer ACK is received, the TxE bit is set and an interrupt is generated if ITEVTEN and ITBUFEN are set. If TxE is set but no new data is written to the data register before the end of the next data send, the BTF bit will be set. SCL will remain low until the BTF is cleared. Reading status register 1 (R16\_I2C1\_STAR1) and then writing data to the data register will clear the BTF bit.

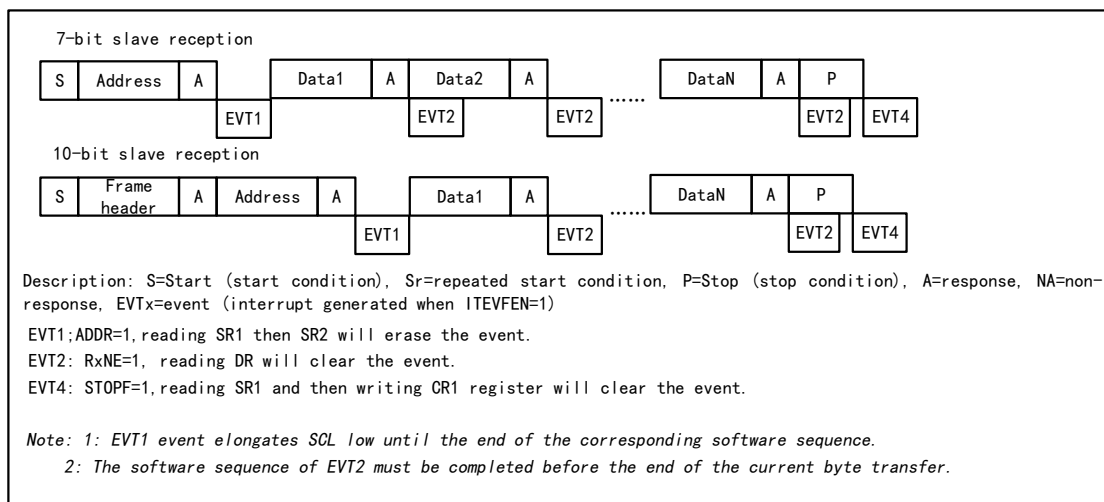

Figure 15-5 Slave transmitter transmission sequence diagram

### Slave receive mode:

After ADDR is cleared, the I2C module stores the data on SDA into the data register via the shift register. After each byte is received, the I2C module sets an ACK bit and sets the RxNE bit, and generates an interrupt if ITEVTEN and ITBUFEN are set. If RxNE is set and the old data is not read before the new data is received, then BTF is set. SCL will remain low until the BTF bit is cleared. Reading status register 1 (R16\_I2C1\_STAR1) and reading the data in the data register will clear the BTF bit.

Figure 15-6 Receiver transmission sequence diagram

The master device will generate a stop condition after the last data byte is transferred. When the I2C module detects a stop event, it will set the STOPF bit, and if the ITEVFEN bit is set, it will also generate an interrupt. The user needs to read the status register (R16\_I2C1\_STAR1) and then write the control register (e.g. reset control word SWRST) to clear it.

## 15.5 Error Conditions

### 15.5.1 Bus Error (BERR)

A bus error will be generated when the I2C module detects an external start or stop event during address or data transfer. When a bus error is generated, the BERR bit is set and an interrupt is generated if ITERREN is set. In slave mode, the data is discarded and the hardware releases the bus. If it is a start signal, the hardware assumes it is a restart signal and starts waiting for an address or stop signal; if it is a stop signal, it operates ahead of normal stop conditions. In master mode, the hardware does not release the bus while not affecting the current transfer, and it is up to the user code to decide whether to abort the transfer.

### 15.5.2 Acknowledge Failure (AF)

An answer error will be generated when the I2C module detects a byte and then no answer. When an answer error is generated: AF will be set and an interrupt will be generated if ITERREN is set; when an AF error is encountered, the hardware must release the bus if the I2C module is working in slave mode and the software must generate a stop event if it is in master mode.

### 15.5.3 Arbitration Lost (ARLO)

An arbitration lost error is generated when the I2C module detects an arbitration lost. When an arbitration loss error is generated: the ARLO bit is set and an interrupt is generated if ITERREN is set; the I2C module switches to slave

mode and no longer responds to transfers initiated against its slave address unless a new start event is initiated by the host; the hardware releases the bus.

### 15.5.4 Overrun/Underrun Error (OVR)

- **Overrun error**

In Slave mode, if the clock extension is disabled and the I2C module is receiving data, an overrun error will occur if a byte of data has been received but the last received data has not been read out. When an overrun error occurs, the last received byte will be discarded and the sender should retransmit the last sent byte.

- **Underrun error**

In Slave mode, if the clock is forbidden to extend and the I2C module is sending data, an underrun error will occur if new data has not been written to the data register before the next byte of the clock comes. In case of an underrun error, the data in the previous data register will be sent twice, and if an underrun error occurs, then the receiver should discard the data received repeatedly. In order not to generate an underrun error, the I2C module should write the data to the data register before the first rising edge of the next byte.

## 15.6 Clock Extension

If clock extension is disabled, then there is a possibility of overrun/underrun errors. However, if clock extension is enabled:

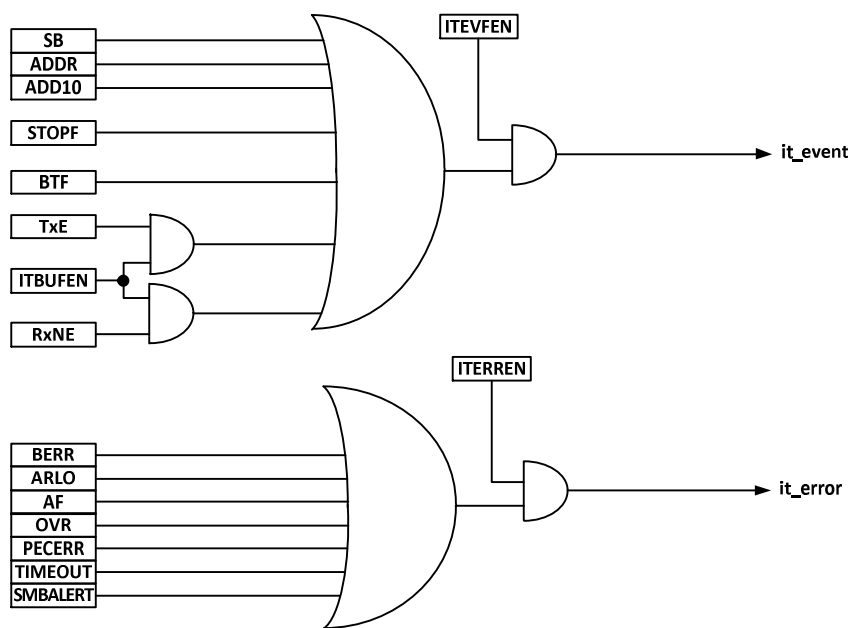

- In transmit mode, if TxE is set and BTF is set, SCL will always be low, always waiting for the user to read the status register and write the data to be sent to the data register.
- In receive mode, if RxNE is set and BTF is set, SCL will remain low after data is received until the user reads the status register and reads the data register.

It can be seen that enabling clock extension can avoid overrun/underrun errors.

## 15.7 Interrupts

Each I2C module has 2 interrupt vectors, event interrupts and error interrupts. Both interrupts support the interrupt sources in Figure 15-7.

Figure 15-7 I2C Interrupt Request

### 15.8 Packet Error Checking

Packet Error Checksum (PEC) is an additional CRC8 checksum step to provide transmission reliability, calculated for each bit of serial data using the following polynomial.

$$C=X^8 +X^2 +X+1$$

The PEC calculation is activated by the ENPEC bit in the control register and is performed on all information bytes, including address and read/write bits. In transmitting, enabling PEC adds a byte of CRC8 calculation result after the last byte of data; while in receiving mode, in the last byte is considered as CRC8 check result, and if it does not match with the internal calculation result, it will reply a NAK, and in case of the main receiver, regardless of the correct check result.

### 15.9 Register Description

Table 15-1 I2C-related registers list

| Name            | Access address | Description            | Reset value |
|-----------------|----------------|------------------------|-------------|
| R16_I2C1_CTLR1  | 0x40005400     | I2C control register 1 | 0x0000      |

## Chapter 16 Serial Peripheral Interface (SPI)

SPI supports data interaction in a 3-wire synchronous serial mode, plus a chip selector line to support hardware switching between Master and Slave modes, and supports communication on a single data line.

### 16.1 Main Features

#### 16.1.1 SPI Features

- Support full-duplex synchronous serial mode
- Support single-wire half-duplex mode
- Support Master mode and Slave mode, multi-slave mode
- Support 8-bit or 16-bit data structures
- Maximum clock frequency supports up to half of  $F_{HCLK}$
- Data order supports MSB or LSB first
- Support hardware or software control of NSS pins
- Hardware CRC checksum support for transmitting and receiving
- Transceiver buffers support DMA transfers
- Support modification of clock phase and polarity

### 16.2 Function Description

#### 16.2.1 Overview

Figure 16-1 SPI structure block diagram

As can be seen from Figure 16-1, the four main SPI-related pins are MISO, MOSI, SCK and NSS. The MISO pin is

the data input pin when the SPI module is operating in Master mode and the data output pin when it is operating in Slave mode. the MOSI pin is the data output pin when it is operating in Master mode and the data input pin when it is operating in Slave mode. the SCK is the clock pin, the clock signal is always output by the host and the slave receives the clock signal and synchronizes the data sending and receiving. the NSS pin is the chip select pin with the following usage.

- 1) NSS controlled by software: when SSM is set and the internal NSS signal is output high or low as determined by SSI, this case is generally used in SPI Master mode.
- 2) NSS is controlled by hardware: when NSS output is enabled, i.e., when SSOE is set, the NSS pin will be actively pulled low when the SPI host sends output outward, and a hardware error will be generated if the NSS pin is pulled low; if SSOE is not set, it can be used in multi-master mode, and if it is pulled low it will be forced into Slave mode and the MSTR bit will be cleared automatically.

The operating mode of the SPI can be configured via CPHA and CPOL; CPHA is set to indicate that the module samples data on the second edge of the clock and the data is latched, CPHA is not set to indicate that the SPI module samples data on the first edge of the clock and the data is latched, and CPOL indicates whether the clock is held high or low when there is no data.

The host and device need to be set to the same SPI mode and the SPE bit needs to be cleared before configuring the SPI mode. the DEF bit determines whether the individual data length of the SP is 8 or 16 bits. the LSBFIRST controls whether the individual data word is preceded by a high bit or a low bit.

Table 16-1 SPI mode differences

|      | Mode 0 | Mode 1 | Mode 2 | Mode 3 |
|------|--------|--------|--------|--------|
| CPOL | 0      | 1      | 1      | 1      |
| CPHA | 0      | 0      | 0      | 1      |

### 16.2.2 Master Mode

The serial clock is generated by SCK when the SPI module is operating in master mode. The following steps are performed to configure into master mode:

The BR[2:0] field of the configuration control register to determine the clock;

Configure the CPOL and CPHA bits to determine the SPI mode;

Configure DEF to determine the data word length;

Configure LSBFIRST to determine the frame format;

Configure the NSS pin, for example by setting the SSOE bit and letting the hardware set the NSS. it is also possible to set the SSM bit and set the SSI bit high;

To set the MSTR bit and the SPE bit, you need to make sure that the NSS is already high at this time.

When data needs to be sent just write the data to be sent to the data register. SPI will send the data from the send buffer to the shift register in parallel, when the data has reached the shift register, the TXE flag will be set, if the TXEIE has been set, then an interrupt will be generated. If the TXE flag position bit needs to fill the data register with data to maintain the complete data flow.

When the receiver receives data, when the last sample clock edge of the data word comes, the data is transferred from the shift register to the receive buffer in parallel, the RXNE bit is set, and an interrupt is generated if the RXNEIE bit was previously set. At this time, the data register should be read as soon as possible to take away the data.

Figure 16-2 SPI master mode read/write mode 0

Figure 16-3 SPI master mode read/write mode 1

Figure 16-4 SPI master mode read/write mode 2

Figure 16-5 SPI master mode read/write mode 3

### 16.2.3 Slave Mode

When the SPI module is operating in slave mode, SCK is used to receive the clock from the host and its own baud rate setting is invalid. To configure into slave mode, proceed as follows.

Configure the DEF bit to set the data bit length.

Configure CPHA to match the host operating mode;

Determine the SPI operating mode based on the transmitting and receiving configurations and CPOL;

If transmitting in slave mode is required, CPOL needs to be set and configured as mode 2 or mode 3, and the host changes the configuration as required;

If only receiving in slave mode is required, only the host CPOL mode needs to be matched;

Configure LSBFIRST to match the host data frame format;

The NSS pin needs to be held low in hardware management mode, if NSS is set to software management (SSM set),

then keep SSI unset.

Clear the MSTR bit and set the SPE bit to enable SPI mode.

During transmission, when the first slave receive sample edge appears in SCK, the slave starts to transmit. The process of transmitting is to move the data in the transmit buffer to the transmit shift register. When the data in the transmit buffer is moved to the shift register, the TXE flag will be set, and if the TXEIE bit was set before, then an interrupt will be generated.

During reception, after the last clock sample edge, the RXNE bit is set, the bytes received by the shift register are transferred to the receive buffer, and the read operation of the read data register can obtain the data in the receive buffer. If RXNEIE is set before RXNE is set, then an interrupt is generated.

Figure 16-6 SPI slave mode read mode 0

Figure 16-7 SPI slave mode read mode 1

Figure 16-8 SPI slave mode read/write mode 2

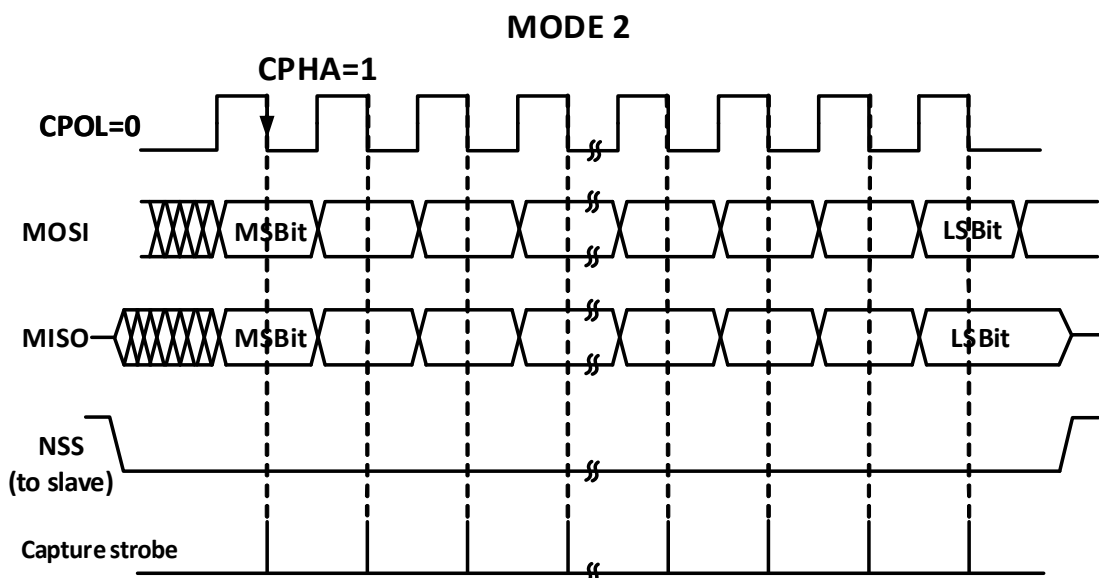

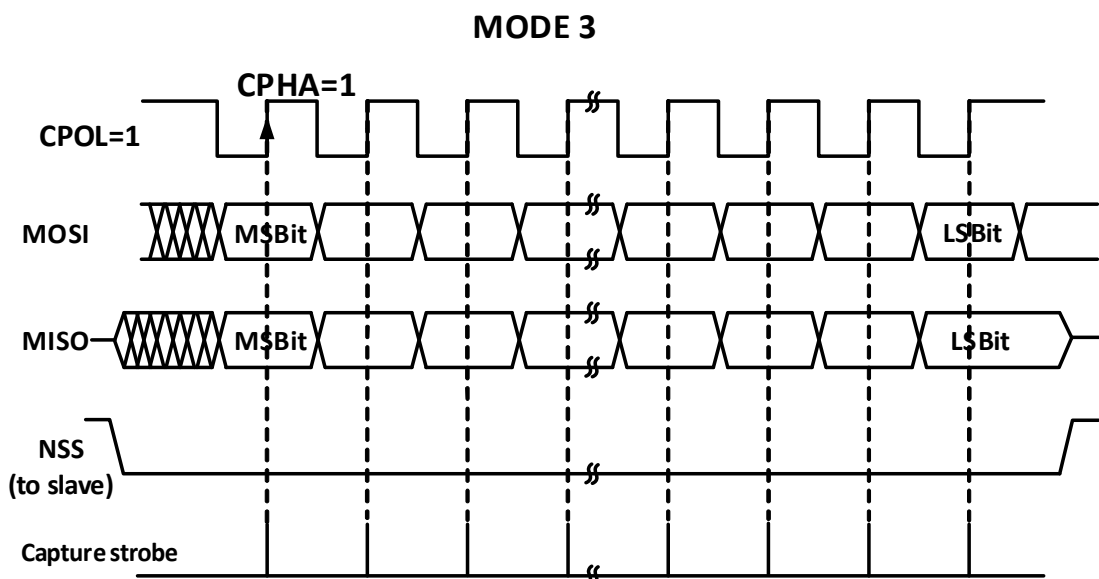

Figure 16-9 SPI slave mode read/write mode 3

### 16.2.4 Simplex Mode

The SPI interface can operate in half-duplex mode, where the master device uses the MOSI pin and the slave device uses the MISO pin for communication. When using half-duplex communication, you need to set BIDIMODE and use BIDIOE to control the transmission direction.

Setting the RXONLY bit in normal full-duplex mode sets the SPI module to receive-only simplex mode, releasing a data pin after RXONLY is set. The SPI can also be set to transmit only mode by ignoring the received data.

### 16.2.5 CRC

The SPI module uses CRC checksum to ensure the reliability of full-duplex communication, and separate CRC calculators are used for data transmitting and receiving. the polynomial for CRC calculation is determined by the

polynomial register, and different calculations are used for 8-bit data width and 16-bit data width, respectively. Setting the CRCEN bit will enable CRC checksum and at the same time will reset the CRC calculator. After the last data byte is transmitted, setting the CRCNEXT bit will transmit the TXCRCR calculator calculation after the current byte is sent, while the CRCERR bit will be set if the last received receive shift register value does not match the locally calculated RXCRCR calculation. Using the CRC checksum requires setting the polynomial calculator and setting the CRCEN bit when configuring the SPI operating mode, and setting the CRCNEXT bit on the last word or half-word to transmit the CRC and perform the receive CRC checksum. Note that the polynomial for the CRC calculation should be unified for both transmitting and receiving.

### 16.2.6 DMA

The SPI module supports the use of DMA to speed up data communication, either by using DMA to fill the transmit buffer or by using DMA to pick up data from the receive buffer in a timely manner. DMA will pick up or send data in a timely manner using RXNE and TXE as signals. DMA can also operate in simplex or CRC mode.

### 16.2.7 Errors

- Master mode fault (MODF)

When the SPI is operating in NSS pin hardware management mode, an external pull-down of the NSS pin occurs; or in NSS pin software management mode, the SSI bit is cleared; or the SPE bit is cleared, causing the SPI to be shut down; or the MSTR bit is cleared and the SPI enters slave mode. If the ERRIE bit is already set, an interrupt is also generated. Steps to clear the MODF bit: First perform a read or write operation to R16\_SPI1\_STATR, and then write R16\_SPI1\_CTLR1.

- Overrun condition

If the host sends data and there is unread data in the receive buffer of the slave device, an overflow error occurs, the OVR bit is set, and an interrupt is also generated if ERRIE is set. Sending an overflow error should restart the current transmission. Reading the data register and then reading the status register will eliminate this bit.

- CRC error

When the received CRC word and the value of RXCRCR do not match, a CRC error will be generated and the CRCERR bit will be set.

### 16.2.8 Interrupts

The SPI module supports five interrupt sources, among which the TXE and RXNE events are set when the TXEIE and RXNEIE bits are set respectively. In addition to the above three errors will also generate interrupts, namely MODF, OVR and CRCERR, after enabling the ERRIE bit, these three errors will also generate error interrupts.

## 16.3 Register Description

Table 16-1 SPI-related registers list

| Name           | Access address | Description            | Reset value |

### 16.3.4 SPI Data Register (SPI1\_Datar)

Offset address: 0x0C

| Bit    | Name     | Access | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Reset value |
|--------|----------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [15:0] | DR[15:0] | RW     | Data register. The data registers are used to store received data or pre-store data to be sent out, so the reading and writing of data registers actually corresponds to the operation of different areas, where reads correspond to the receive buffer and writes to the send buffer. Data can be received and sent in 8 or 16 bits, and it is necessary to determine how many bits of data to use before transmission. When using 8 bits for data transmission, only the lower 8 bits of the data register are used and the higher 8 bits are forced to 0 for reception; using a 16-bit data structure causes all 16 bits of the data register to be used. | 0           |

### 16.3.5 SPI Polynomial Register (SPI1\_CRCCR)

Offset address: 0x10

| Bit    | Name          | Access | Description                                                                    | Reset value |
|--------|---------------|--------|--------------------------------------------------------------------------------|-------------|
| [15:0] | CRCPOLY[15:0] | RW     | CRC polynomial. This field defines the polynomial used in the CRC calculation. | 7           |

### 16.3.6 SPI Receive CRC Register (SPI1\_RCRCR)

Offset address: 0x14

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

| Bit    | Name        | Access | Description                                                                                                                                                                                                                                                                                                                                                          | Reset value |
|--------|-------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [15:0] | RXCRC[15:0] | RO     | Receive CRC value. Stores the result of the calculated CRC checksum of the received byte. Setting CRCEN resets this register. The calculation uses the polynomial used by CRCPOLY; only the lower 8 bits are involved in the calculation in 8-bit mode and all 16 bits are involved in the calculation in 16-bit mode. This register needs to be read when BSY is 0. | 0           |

## Chapter 17 Operational Amplifiers (OPA) and Comparators (CMP)

The module contains 2 independently configurable operational amplifiers (OPA or PGA) and 3 independently configurable voltage comparators (CMP), where the operational amplifiers (OPA or PGA) support gain selection and can also be adapted for use as voltage comparators.

The inputs and outputs of each op-amp are connected to I/O ports with selectable input pins or gain, and the output pins can be optionally configured to the general purpose I/O port or alternate as I/O for the ADC sample channels, supporting the amplification of small external analogue signals into the ADC for small signal ADC conversion.

The input and output of each voltage comparator are connected to the I/O port and the input pins are selectable and the output pins can be optionally configured to the general purpose I/O port or alternate as TIM internal sampling channels (Without taking up I/O pins).

### 17.1 Main Features

- OPA input pin or channel selectable
- OPA output pins selectable for general purpose I/O ports or ADC sampling channels
- OPA supports positive input polling
- OPA supports PGA gain selection
- CMP input pin selectable, negative input channel selectable common pins
- CMP output pins selectable for general-purpose I/O port or TIM internal sample channel
- 1 interrupt vector

### 17.2 Function Description

#### 17.2.1 OPA

Configuring `MODEx` in the `OPA_CTLR1` register selects the output channel of the `OPAx` as an ADC sample channel or a normal I/O port, configuring `PSELx` in the `OPA_CTLR1` register selects the positive input pin of the `OPAx`, and configuring `NSELx` in the `OPA_CTLR1` register selects the negative input channel of the `OPAx` or the gain when used as a PGA.

#### 17.2.2 Polling of Positive OPA Inputs

The polling function of OPA can be implemented by selecting `OPA_P0/OPA_P1/OPA_P2` at regular intervals and selecting all P-terminals in turn; the polling `OPAx` can be selected by configuring the `POLL_EN` bit in the `OPA_CFGR` register.

The number of channels to be polled can be configured via `POLLx_NUM` in the `OPA_CFGR` register, and the polling interval can be configured via `POLL_VLU` in the `OPA_CFGR` register.

#### 17.2.3 CMP

To enable the corresponding `CMPx`, set `ENx` in the `OPA_CTLR2` register. Configure `MODEx` in the `OPA_CTLR2` register to select the output channel of the `CMPx` as a normal I/O port or an internal timer channel. Configure `PSELx` in the `OPA_CTLR2` register to select the positive input pin of the `CMPx`, and configure `NSELx` in the `OPA_CTLR2` register to select the negative input pin of the `CMPx`.

*Note: For detailed input and output pins of each OPA and CMP, refer to the pin descriptions in the datasheet.*

## 17.3 Register Description

Table 17-1 OPA-related registers list

| Name          | Access address | Description                  | Reset value |
|---------------|----------------|------------------------------|-------------|
| R16_OPA_CFGR1 | 0x40026000     | OPA configuration register 1 | 0x0080      |

| Bit    | Name          | Access | Description                                                                                     | Reset value |
|--------|---------------|--------|-------------------------------------------------------------------------------------------------|-------------|
| [31:0] | CMP_KEY[31:0] | RW     | CMP keys, used to enter the CMP unlock key include:<br>KEY1 = 0x45670123;<br>KEY2 = 0xCDEF89AB. | X           |

### 17.3.7 POLL Unlock Key Register (POLL\_KEY)

Offset address: 0x14

| Bit    | Name           | Access | Description                                                                                       | Reset value |
|--------|----------------|--------|---------------------------------------------------------------------------------------------------|-------------|
| [31:0] | POLL_KEY[31:0] | RW     | POLL keys, used to enter the POLL unlock key include:<br>KEY1 = 0x45670123;<br>KEY2 = 0xCDEF89AB. | X           |

## Chapter 18 USB Full-speed Host/Device Controller (USB FS)

### 18.1 Introduction to USB Controller

The chip is embedded with a USB controller and transceiver with the following features:

- Dual role controller supporting USB Host function and USB Device function.
- Comply with the On-The-Go Supplement to the USB2.0 specification and supports USB2.0 full-speed 12Mbps or low-speed 1.5Mbps in both host and device modes.
- Support software HNP and SRP protocols.
- Support USB control transfers, bulk transfers, interrupt transfers, and synchronous/real-time transfers.
- Support packets up to 64 bytes, built-in FIFO, interrupt and DMA support.

### 18.2 Register Description

USB related registers are divided into 3 sections, some of which are alternate in host and device mode.

- USB Global Register
- USB Device Control Register
- USB Host Control Register

#### 18.2.1 Global Register Description

Table 18-1 USB FS-related registers list

| Name          | Access address | Description                                | Reset value |
|---------------|----------------|--------------------------------------------|-------------|
| R8_BASE_CTRL  | 0x40023400     | USB control register                       | 0x06        |
| R8_INT_EN     | 0x40023402     | USB interrupt enable register              | 0x00        |
| R8_DEV_ADDR   | 0x40023403     | USB device address register                | 0x00        |
| R8_MIS_ST     | 0x40023405     | USB miscellaneous status register          | 0xXX        |
| R8_INT_FG     | 0x40023406     | USB interrupt flag register                | 0x20        |
| R8_INT_ST     | 0x40023407     | USB interrupt status register              | 0xXX        |
| R16_RX_LEN    | 0x40023408     | USB receive length register                | 0xXX        |
| R8_UEP4_1_MOD | 0x4002340C     | Endpoint 1 and 4 mode control registers    | 0x00        |
| R8_UEP2_3_MOD | 0x4002340D     | Endpoint 2 and 3 mode control registers    | 0x00        |
| R8_UEP567_MOD | 0x4002340E     | Endpoint 5, 6 and 7 mode control registers | 0x00        |

##### 18.2.1.1 USB Control Register (R8\_BASE\_CTRL)

| Bit   | Name            | Access | Description                                                                            | Reset value |
|-------|-----------------|--------|----------------------------------------------------------------------------------------|-------------|
| 7     | RB_UC_HOST_MODE | RW     | USB operating mode selection bits:<br>1: Host mode (HOST);<br>0: Device mode (DEVICE). | 0           |
| 6     | RB_UC_LOW_SPEED | RW     | USB low-speed enable bit:<br>1: Low-speed enabled;<br>0: Low-speed disabled.           | 0           |
| [5:4] | RB_SYS_MODE     | RW     | Test mode in host mode.                                                                | 0           |
| 3     | RB_UC_INT_BUSY  | RW     | USB transfer completion interrupt flag not                                             | 0           |

|   |               |    |                                                                                                                                                                                                           |   |
|---|---------------|----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
|   |               |    | cleared to zero Auto pause enable bit:<br>1: Auto pause before interrupt flag UIF_TRANSFER is cleared, auto answer busy NAK in device mode, auto pause subsequent transfers in host mode;<br>0: No pause. |   |
| 2 | RB_UC_RST_SIE | RW | USB protocol processor software reset control bits:<br>1: Forced reset of the USB protocol processor (SIE), requiring a software reset;<br>0: No reset.                                                   | 1 |
| 1 | RB_UC_CLR_ALL | RW | USB FIFO and interrupt flag clear: 1<br>1: Clears the USB interrupt flag and FIFO, requires software clearing;<br>0: Not cleared.                                                                         | 1 |
| 0 | RB_UC_DMA_EN  | RW | Enables DMA for USB, this bit must be set to 1 in normal transfer mode:<br>1: Enables the DMA function and the DMA interrupt;<br>0: Disables DMA.                                                         | 0 |

### 18.2.1.2 USB Interrupt Enable Register (R8\_INT\_EN)

| Bit | Name            | Access | Description                                                                                                                  | Reset value |
|-----|-----------------|--------|------------------------------------------------------------------------------------------------------------------------------|-------------|
| 7   | Reserved        | RO     | Reserved.                                                                                                                    | 0           |
| 6   | RB_UIE_DEV_NAK  | RW     | USB device mode, receive NAK interrupt:<br>1: Enable the corresponding interrupt;<br>0: Disable the corresponding interrupt. | 0           |
| 5   | RB_UID_1_WIRE   | RW     | USB 1-wire mode enable:<br>1: Enable; 0: Disable.                                                                            | 0           |
| 4   | RB_UIE_FIFO_OV  | RW     | FIFO overflow interrupt:<br>1: Enable interrupt; 0: Disable interrupt.                                                       | 0           |
| 3   | RB_UIE_SOF_ACT  | RW     | USB host mode, SOF receive completion interrupt:<br>1: Enable interrupt; 0: Disable interrupt.                               | 0           |
| 2   | RB_UIE_SUSPEND  | RW     | USB bus suspend or wakeup event interrupt:<br>1: Enable interrupt; 0: Disable interrupt.                                     | 0           |
| 1   | RB_UIE_TRANSFER | RW     | USB transfer (excluding SETUP transaction) completion interrupt:<br>1: Enable interrupt; 0: Disable interrupt.               | 0           |
| 0   | RB_UIE_DETECT   | RW     | USB host mode, USB device connect or disconnect event interrupt:<br>1: Enable interrupt; 0: Disable interrupt.               | 0           |
|     | RB_UIE_BUS_RST  | RW     | USB device mode, USB bus reset event interrupt:                                                                              | 0           |

|  |  |  |                                            |  |
|--|--|--|--------------------------------------------|--|
|  |  |  | 1: Enable interrupt; 0: Disable interrupt. |  |
|--|--|--|--------------------------------------------|--|

### 18.2.1.3 USB Device Address Register (R8\_DEV\_ADDR)

| Bit   | Name          | Access | Description                                                                                                                       | Reset value |
|-------|---------------|--------|-----------------------------------------------------------------------------------------------------------------------------------|-------------|
| 7     | Reserved      | RO     | Reserved.                                                                                                                         | 0           |
| [6:0] | MASK_USB_ADDR | RW     | Host mode is the address or HUB address of the USB device currently in operation;<br>Device mode: the address of that USB itself. | 0           |

### 18.2.1.4 USB Miscellaneous Status Register (R8\_MIS\_ST)

| Bit | Name              | Access | Description                                                                                                                                                                                                 | Reset value |
|-----|-------------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 7   | RB_UMS_SOF_PRES   | RO     | SOF packet presage status in USB host mode:<br>1: SOF packet is about to be transmitted, if there are other USB packets at this time, it will be automatically delayed;<br>0: No SOF packet is transmitted. | X           |
| 6   | RB_UMS_SOF_ACT    | RO     | SOF packet transfer status in USB host mode:<br>1: SOF packet is being transmitted;<br>0: Transmit complete or idle.                                                                                        | X           |
| 5   | RB_UMS_SIE_FREE   | RO     | USB protocol handler free:<br>1: The protocol device is free;<br>0: Busy, USB transfer in progress.                                                                                                         | 1           |
| 4   | RB_UMS_R_FIFO_RDY | RO     | USB receive FIFO data ready:<br>1: The receive FIFO is not empty;<br>0: The receive FIFO is empty.                                                                                                          | 0           |
| 3   | RB_UMS_BUS_RST    | RO     | USB bus reset:<br>1: The current USB bus is in reset state;<br>0: The current USB bus is in a non-reset state.                                                                                              | X           |
| 2   | RB_UMS_SUSPEND    | RO     | USB suspend:<br>1: The USB bus is in a suspended state, and there is no USB activity for a period of time;<br>0: The USB bus is in a non-suspend state.                                                     | 0           |
| 1   | RB_UMS_DM_LEVEL   | RO     | In USB host mode, level state of the DM pin when the device is just connected to the USB port is used to judge the speed:<br>1: High level/low-speed;<br>0: Low level/full-speed.                           | 0           |

### 18.2.1.5 USB Interrupt Flag Register (R8\_INT\_FG)

| Bit | Name            | Access | Description                                                                                                                                                                                | Reset value |
|-----|-----------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 7   | RB_U_IS_NAK     | RO     | NAK response interrupt flag bit in USB device mode, same as RB_U_IS_NAK:<br>1: Response to NAK during the current USB transfer;<br>0: No event.                                            | 0           |
| 6   | TOG_MATCH_SYNC  | RO     | Toggle of the received packet with the set expectation value after the USB transaction reception is completed.<br>Matching status bits:<br>1: Toggle matched;<br>0: Toggle does not match. | 0           |
| 5   | RB_U_SIE_FREE   | RO     | USB Protocol Handler free:<br>1: USB idle;<br>0: Busy, USB transfer in progress.                                                                                                           | 1           |
| 4   | RB_UIF_FIFO_OV  | RW     | USB FIFO overflow interrupt flag, write 1 to clear:<br>1: FIFO overflow trigger;<br>0: No event.                                                                                           | 0           |
| 3   | RB_UIF_HST_SOF  | RW     | SOF timer interrupt flag in USB host mode, write 1 to clear:<br>1: SOF packet transmission completion trigger;<br>0: No event.                                                             | 0           |
| 2   | RB_UIF_SUSPEND  | RW     | USB bus suspend or wake-up event interrupt flag, write 1 to clear:<br>1: Triggered by USB suspend event or wake-up event;<br>0: No event.                                                  | 0           |
| 1   | RB_UIF_TRANSFER | RW     | USB transfer completion interrupt flag, write 1 to clear:<br>1: Trigger when a USB transfer is completed;<br>0: No event.                                                                  | 0           |
| 0   | RB_UIF_DETECT   | RW     | In USB host mode, USB device connect or disconnect event interrupt flag, write 1 to clear:<br>1: Detected USB device connection or disconnection trigger;<br>0: No event.                  | 0           |

|  |                |    |                                                                                                                                  |   |
|--|----------------|----|----------------------------------------------------------------------------------------------------------------------------------|---|
|  | RB_UIF_BUS_RST | RW | In USB device mode, USB bus reset event interrupt flag bit, write 1 to clear:<br>1: USB bus reset event trigger;<br>0: No event. | 0 |
|--|----------------|----|----------------------------------------------------------------------------------------------------------------------------------|---|

### 18.2.1.6 USB Interrupt Status Register (R8\_INT\_ST)

| Bit   | Name           | Access | Description                                                                                                                                                                        | Reset value |
|-------|----------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 7     | SETUP_ACT      | RO     | SETUP transaction complete<br>1: SETUP transaction complete;<br>0: No event.                                                                                                       | 0           |
| 6     | RB_UIS_TOG_OK  | RO     | Toggle of the received packet after the USB transaction reception is completed with the set expectation<br>Match status bits:<br>1: Toggle matched;<br>0: Toggle does not match.   | 0           |
| [5:4] | MASK_UIS_TOKEN | RO     | In device mode, the token PID identifier of the current USB transfer transaction.                                                                                                  | XXb         |
| [3:0] | MASK_UIS_ENDP  | RO     | In device mode, the endpoint number of the current USB transfer transaction.                                                                                                       | XXXXb       |
|       | MASK_UIS_H_RES | RO     | In host mode, the response PID identifier of the current USB transmission transaction, 0000 means the device has no response or timed out; other values indicate the response PID. | XXXXb       |

Note: MASK\_UIS\_TOKEN is used in USB device mode to identify the token PID of the current USB transmission transaction: 00 for OUT packets; 01 reserved; 10 for IN packets; 11 for SETUP packets.

MASK\_UIS\_H\_RES is only valid in host mode. In host mode, if the host sends an OUT/SETUP token packet, this PID is either a handshake packet ACK/NAK/STALL, or the device has no answer/timeout. If the host sends an IN token packet, this PID is either the packet PID (DATA0/DATA1) or the handshake packet PID.

### 18.2.1.7 USB Receive Length Register (R16\_RX\_LEN)

| Bit    | Name       | Access | Description                                                   | Reset value |
|--------|------------|--------|---------------------------------------------------------------|-------------|
| [15:7] | Reserved   | RO     | Reserved.                                                     | 0           |
| [6:0]  | USB_RX_LEN | RO     | The current number of data bytes received by the USB endpoint | X           |

### 18.2.1.8 Endpoint 1 and 4 mode controller (R8\_UEP4\_1\_MOD)

| Bit | Name     | Access | Description                 | Reset value |
|-----|----------|--------|-----------------------------|-------------|
| 7   | EP1_R_EN | RW     | Endpoint 1 receive enable.  | 0           |
| 6   | EP1_T_EN | RW     | Endpoint 1 transmit enable. | 0           |
| 5   | Reserved | RO     | Reserved                    | 0           |

|       |             |    |                                     |   |
|-------|-------------|----|-------------------------------------|---|
| 4     | EP1_BUF_MOD | RW | Endpoint 1 buffer mode control bit. | 0 |
| 3     | EP4_R_EN    | RW | Endpoint 4 receive enable.          | 0 |
| 2     | EP4_T_EN    | RW | Endpoint 4 transmit enable.         | 0 |
| [1:0] | Reserved    | RO | Reserved                            | 0 |

The combination of EP4\_R\_EN and EP4\_T\_EN configures the data buffer mode for USB endpoints 0 and 4, as shown in the following table:

Table 18-2 Endpoint 0 and 4 buffer modes

| EP4_R_EN | EP4_T_EN | Description: Low to high with UEP0_DMA as starting address                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0        | 0        | Endpoint 0 single 64-byte send/receive common buffer (IN and OUT).                                                                                                                                                                                                                                                                                                                                                                                              |
| 1        | 0        | Endpoint 0 single 64-byte send/receive common buffer; Endpoint 4 single 64-byte receive buffer (OUT)                                                                                                                                                                                                                                                                                                                                                            |
| 0        | 1        | Endpoint 0 single 64-byte send/receive common buffer; Endpoint 4 single 64-byte send buffer (IN)                                                                                                                                                                                                                                                                                                                                                                |

### 18.2.1.10 Endpoint 5, 6 and 7 mode controller (R8\_UEP567\_MOD)

| Bit   | Name     | Access | Description                 | Reset value |
|-------|----------|--------|-----------------------------|-------------|
| [7:6] | Reserved | RO     | Reserved.                   | 0           |
| 5     | EP7_R_EN | RW     | Endpoint 7 receive enable.  | 0           |
| 4     | EP7_T_EN | RW     | Endpoint 7 transmit enable. | 0           |
| 3     | EP6_R_EN | RW     | Endpoint 6 receive enable.  | 0           |
| 2     | EP6_T_EN | RW     | Endpoint 6 transmit enable. | 0           |
| 1     | EP5_R_EN | RW     | Endpoint 5 receive enable.  | 0           |
| 0     | EP5_T_EN | RW     | Endpoint 5 transmit enable. | 0           |

## 18.2.2 USB Device Register Description

The USB FS module provides a total of 8 sets of bidirectional endpoints from endpoints 0-7 in USB device mode, and the maximum packet length for all endpoints is 64 bytes.

- Endpoint 0 is the default endpoint, which supports control transmission and shares a 64-byte data buffer between transmit and receive.
- Endpoints 1-7 each include a transmit endpoint IN and a receive endpoint OUT, each with a separate data buffer for transmit and receive, and support bulk, interrupt and real-time/synchronous transfers.
- Endpoint 0 has a separate DMA address, shared between transmit and receive, and endpoints 1-7 each have a DMA address for transmit and receive. The data buffer mode can be set to double buffer or single buffer by entering the R32\_UEPn\_BUF\_MOD register. If the double buffer mode is used, the endpoint can only use single direction transmission.
- Each set of endpoints has transceiver control registers R8\_UEPn\_TX\_CTRL, R8\_UEPn\_RX\_CTRL and transmit length registers R16\_UEPn\_T\_LEN and R32\_UEPn\_\*\_DMA (n=0~7), which are used to configure the synchronous trigger bits for that endpoint, the response to OUT transactions and IN transactions, and the length of the transmitted data. response, and the length of data sent, etc.

The USB bus pull-up resistor necessary as a USB device can be set by software at any time to enable or disable it. When RB\_UC\_DEV\_PU\_EN in USB control register R8\_USB\_CTRL is set to 1, the controller internally connects a pull-up resistor for the DP/DM pin of the USB bus according to the speed setting of RB\_UC\_SPEED\_TYPE and enables the USB device function.

When a USB bus reset, USB bus hang or wake-up event is detected, or when the USB has successfully processed a data send or data receive, the USB protocol processor sets the corresponding interrupt flag and, if interrupt enable is on, also generates the corresponding interrupt request. The application can query and analyse the interrupt flag register R8\_USB\_INT\_FG either directly or in the USB interrupt service program and process it accordingly according to RB\_UIF\_BUS\_RST and RB\_UIF\_SUSPEND; and, if RB\_UIF\_TRANSFER is valid, then it also needs to continue to analyze the USB interrupt status register R8\_USB\_INT\_ST and process accordingly according to the current endpoint number MASK\_UIS\_ENDP and the current transaction token PID identification MASK\_UIS\_TOKEN. If the synchronization trigger bit RB\_UEP\_R\_TOG is set in advance for each endpoint's OUT transaction, then it can be judged by RB\_U\_TOG\_OK or RB\_UIS\_TOG\_OK whether the synchronization trigger bit of the currently received packet matches the synchronization trigger bit of that endpoint; if the data is synchronized, the data is valid; if the data is not synchronized, the data should be discarded. After each USB transmit or receive interrupt is processed, the corresponding endpoint's sync trigger bit should be correctly modified for the next sent packet or the next received packet to detect if it is synchronous; in addition, setting RB\_UEP\_T\_TOG\_AUTO or RB\_UEP\_R\_TOG\_AUTO enables the corresponding sync trigger bit to be automatically modified after a successful transmit or receive (flip or self-decrease).

The data ready to be sent by each endpoint is in its own buffer, and the length of the data ready to be sent is set independently in R16\_UEPn\_T\_LEN; the data received by each endpoint is in its own buffer, but the length of the data received is in the USB receive length register R16\_USB\_RX\_LEN, which can be distinguished according to the current endpoint number during a USB receive interrupt.

Table 18-3 Device-related registers list

| Name         | Access address | Description                               | Reset value |
|--------------|----------------|-------------------------------------------|-------------|
| R8_UDEV_CTRL | 0x40023401     | USB device physical port control register | 0xX0        |
| R32_UEP0_DMA | 0x40023410     | Start address of endpoint 0 buffer        | 0xFFFFFFFF  |

|                 |            |                                                  |            |
|-----------------|------------|--------------------------------------------------|------------|
| R32_UEP1_DMA    | 0x40023414 | Start address of endpoint 1 buffer               | 0xFFFFFFFF |
| R32_UEP2_DMA    | 0x40023418 | Start address of endpoint 2 buffer               | 0xFFFFFFFF |
| R32_UEP3_DMA    | 0x4002341C | Start address of endpoint 3 buffer               | 0xFFFFFFFF |
| R32_UEP0_CTRL   | 0x40023420 | Endpoint 0 transmit length and control registers | 0x000000XX |
| R16_UEP0_TX_LEN | 0x40023420 | Endpoint 0 transmit length register              | 0x00XX     |
| R16_UEP0_CTRL_H | 0x40023422 | Endpoint 0 control register                      | 0x0000     |

### 18.2.2.1 USB Device Physical Port Control Register (R8\_UDEV\_CTRL)

| Bit | Name         | Access | Description                          | Reset value |
|-----|--------------|--------|--------------------------------------|-------------|
| 7   | RB_UD_PD_DIS | RW     | USB device port UDP/UDM pin internal | 1           |

|   |                 |    |                                                                                                                                                                                                                                                                                         |   |
|---|-----------------|----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
|   |                 |    | pull-down resistor control bits:<br>1: Disable the internal pull-down;<br>0: Enable internal pull-down, also used in GPIO mode to provide pull-down resistor.<br><i>Note: MODE and CNF of GPIOC_CFGXR and GPIOC_OUTDR have been changed to set the pull-down, this bit is reserved.</i> |   |
| 6 | Reserved        | RO | Reserved.                                                                                                                                                                                                                                                                               | 0 |
| 5 | RB_UD_DP_PIN    | RO | Current UDP pin status:<br>1: High;<br>0: low.                                                                                                                                                                                                                                          | X |
| 4 | RB_UD_DM_PIN    | RO | Current UDM pin state:<br>1: High;<br>0: low.                                                                                                                                                                                                                                           | X |
| 3 | Reserved        | RO | Reserved.                                                                                                                                                                                                                                                                               | 0 |
| 2 | RB_UD_LOW_SPEED | RW | USB device physical port low speed mode enable bit:<br>1: Select 1.5Mbps low speed mode;<br>0: Select 12Mbps full speed mode.                                                                                                                                                           | 0 |
| 1 | RB_UD_GP_BIT    | RW | USB device mode general flag bit, user-defined.                                                                                                                                                                                                                                         | 0 |
| 0 | RB_UD_PORT_EN   | RW | USB device physical port enable bit:<br>1: Enable the physical port;<br>0: Disable the physical port.                                                                                                                                                                                   | 0 |

#### 18.2.2.2 Start Address of Endpoint 0 Buffer (R32\_UEP0\_DMA)

| Bit     | Name         | Access | Description                                                                                                    | Reset value |
|---------|--------------|--------|----------------------------------------------------------------------------------------------------------------|-------------|
| [31:15] | Reserved     | RO     | Reserved.                                                                                                      | 0           |
| [14:0]  | EP0_BUF_ADDR | RW     | Start address of the endpoint 0 buffer.<br>The lower 15 bits are valid and the address must be 4-byte aligned. | 0           |

*Note: The transceiver enable signal for endpoint 0 is always active.*

#### 18.2.2.3 Start Address of Endpoint 1 Buffer (R32\_UEP1\_DMA)

| Bit     | Name         | Access | Description                                                                                                    | Reset value |
|---------|--------------|--------|----------------------------------------------------------------------------------------------------------------|-------------|
| [31:15] | Reserved     | RO     | Reserved.                                                                                                      | 0           |
| [14:0]  | EP0_BUF_ADDR | RW     | Start address of the endpoint 1 buffer.<br>The lower 15 bits are valid and the address must be 4-byte aligned. | 0           |

*Note: The transceiver enable signal for endpoint 1 is always active.*

#### 18.2.2.4 Start Address of Endpoint 2 Buffer (R32\_UEP2\_DMA)

| Bit | Name | Access | Description | Reset value |
|-----|------|--------|-------------|-------------|
|-----|------|--------|-------------|-------------|

|         |              |    |                                                                                                                |   |
|---------|--------------|----|----------------------------------------------------------------------------------------------------------------|---|
| [31:15] | Reserved     | RO | Reserved.                                                                                                      | 0 |
| [14:0]  | EP0_BUF_ADDR | RW | Start address of the endpoint 2 buffer.<br>The lower 15 bits are valid and the address must be 4-byte aligned. | 0 |

Note: The transceiver enable signal for endpoint 2 is always active.

#### 18.2.2.5 Start Address of Endpoint 3 Buffer (R32\_UEP3\_DMA)

| Bit     | Name         | Access | Description                                                                                                    | Reset value |
|---------|--------------|--------|----------------------------------------------------------------------------------------------------------------|-------------|
| [31:15] | Reserved     | RO     | Reserved.                                                                                                      | 0           |
| [14:0]  | EP0_BUF_ADDR | RW     | Start address of the endpoint 3 buffer.<br>The lower 15 bits are valid and the address must be 4-byte aligned. | 0           |

Note: The transceiver enable signal for endpoint 3 is always active.

#### 18.2.2.6 Endpoint 0 Transmit Length and Control Registers (R32\_UEP0\_CTRL)

| Bit     | Name            |
|---------|-----------------|
| [31:16] | R16_UEP0_CTRL_H |
| [15:0]  | R16_UEP0_TX_LEN |

#### 18.2.2.7 Endpoint 0 transmit length register (R16\_UEP0\_TX\_LEN)

| Bit    | Name      | Access | Description                                    | Reset value |
|--------|-----------|--------|------------------------------------------------|-------------|
| [15:7] | Reserved  | RO     | Reserved.                                      | 0           |
| [6:0]  | EP0_T_LEN | RW     | The number of bytes transmitted by endpoint 0. | 0           |

#### 18.2.2.8 Endpoint 0 Control Register (R16\_UEP0\_CTRL\_H)

| Bit    | Name           | Access | Description                                                                                                                                                                             | Reset value |
|--------|----------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [15:8] | Reserved       | RO     | Reserved.                                                                                                                                                                               | 0           |
| 7      | EP0_R_TOG      | RW     | Sync trigger bits prepared by the receiver of USB endpoint 0 (Processing OUT transactions):<br>1: Expects DATA1;<br>0: Expects DATA0.<br>Not valid for real-time/synchronous transfers. | 0           |
| 6      | EP0_T_TOG      | RW     | Sync trigger bits prepared by the sender of USB endpoint 0 (Handling IN transactions):<br>1: Transmit DATA1;<br>0: Transmit DATA0.                                                      | 0           |
| [5:4]  | Reserved       | RO     | Reserved.                                                                                                                                                                               | 0           |
| [3:2]  | EP0_R_RES[1:0] | RW     | The receiver at endpoint 0 controls the response to an OUT transaction:<br>00: Data ready and expects ACK;<br>01: Answer NYET;                                                          | 0           |

|       |                |    |                                                                                                                                                                                                                                                               |   |
|-------|----------------|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
|       |                |    | 10: Response NAK or busy;<br>11: Answer STALL or error.<br>Not valid for real-time/synchronous transfers.                                                                                                                                                     |   |
| [1:0] | EPO_T_RES[1:0] | RW | Endpoint 0 transmitter response control bits for IN transactions<br>00: Expect an answer ACK;<br>01: Expect an answer NYET;<br>10: Expect an answer NAK or busy;<br>11: Expect an answer STALL or error.<br>Not valid for real-time/synchronous transmission. | 0 |

### 18.2.2.9 Endpoint 1 Transmit Length and Control Registers (R32\_UEP1\_CTRL)

| Bit     | Name            |
|---------|-----------------|
| [31:16] | R16_UEP1_CTRL_H |
| [15:0]  | R16_UEP1_TX_LEN |

### 18.2.2.10 Endpoint 1 Transmit Length Register (R16\_UEP1\_TX\_LEN)

| Bit    | Name      | Access | Description                                    | Reset value |
|--------|-----------|--------|------------------------------------------------|-------------|
| [15:7] | Reserved  | RO     | Reserved.                                      | 0           |
| [6:0]  | EPO_T_LEN | RW     | The number of bytes transmitted by endpoint 1. | 0           |

### 18.2.2.11 Endpoint 1 Control Register (R16\_UEP1\_CTRL\_H)

| Bit    | Name         | Access | Description                                                                                                                                                                                                            | Reset value |
|--------|--------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [15:8] | Reserved     | RO     | Reserved.                                                                                                                                                                                                              | 0           |
| 7      | EP1_R_TOG    | RW     | Sync trigger bits prepared by the receiver of USB endpoint 1 (Processing OUT transactions):<br>1: Expects DATA1;<br>0: Expects DATA0.<br>Not valid for real-time/synchronous transfers.                                | 0           |
| 6      | EP1_T_TOG    | RW     | Sync trigger bits prepared by the sender of USB endpoint 1 (Handling IN transactions):<br>1: Transmit DATA1;<br>0: Transmit DATA0.                                                                                     | 0           |
| 5      | Reserved     | RO     | Reserved.                                                                                                                                                                                                              | 0           |
| 4      | EP1_TOG_AUTO | RW     | Synchronization Trigger Bit Auto Flip Enable Control Bit:<br>1: Auto flip after successful data sending and receiving;<br>0: not auto-flip, can be switched manually.<br><i>Note: Endpoint 0 This bit is reserved.</i> | 0           |

|       |                |    |                                                                                                                                                                                                                                                               |   |
|-------|----------------|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
| [3:2] | EP1_R_RES[1:0] | RW | The receiver at endpoint 1 controls the response to an OUT transaction:<br>00: Data ready and expects ACK;<br>01: Answer NYET;<br>10: Response NAK or busy;<br>11: Answer STALL or error.<br>Not valid for real-time/synchronous transfers.                   | 0 |
| [1:0] | EP1_T_RES[1:0] | RW | Endpoint 1 transmitter response control bits for IN transactions<br>00: Expect an answer ACK;<br>01: Expect an answer NYET;<br>10: Expect an answer NAK or busy;<br>11: Expect an answer STALL or error.<br>Not valid for real-time/synchronous transmission. | 0 |

#### 18.2.2.12 Endpoint 2 Transmit Length and Control Registers (R32\_UEP2\_CTRL)

| Bit     | Name            |
|---------|-----------------|
| [31:16] | R16_UEP2_CTRL_H |
| [15:0]  | R16_UEP2_TX_LEN |

#### 18.2.2.13 Endpoint 2 Transmit Length Register (R16\_UEP2\_TX\_LEN)

| Bit    | Name      | Access | Description                                    | Reset value |
|--------|-----------|--------|------------------------------------------------|-------------|
| [15:7] | Reserved  | RO     | Reserved.                                      | 0           |
| [6:0]  | EP0_T_LEN | RW     | The number of bytes transmitted by endpoint 2. | 0           |

#### 18.2.2.14 Endpoint 2 Control Register (R16\_UEP2\_CTRL\_H)

| Bit    | Name         | Access | Description                                                                                                                                                                             | Reset value |
|--------|--------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [15:8] | Reserved     | RO     | Reserved.                                                                                                                                                                               | 0           |
| 7      | EP2_R_TOG    | RW     | Sync trigger bits prepared by the receiver of USB endpoint 2 (Processing OUT transactions):<br>1: Expects DATA1;<br>0: Expects DATA0.<br>Not valid for real-time/synchronous transfers. | 0           |
| 6      | EP2_T_TOG    | RW     | Sync trigger bits prepared by the sender of USB endpoint 2 (Handling IN transactions):<br>1: Transmit DATA1;<br>0: Transmit DATA0.                                                      | 0           |
| 5      | Reserved     | RO     | Reserved.                                                                                                                                                                               | 0           |
| 4      | EP2_TOG_AUTO | RW     | Synchronization Trigger Bit Auto Flip Enable Control Bit:                                                                                                                               | 0           |

|       |                |    |                                                                                                                                                                                                                                                               |   |
|-------|----------------|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
|       |                |    | 1: Auto flip after successful data sending and receiving;<br>0: not auto-flip, can be switched manually.<br><i>Note: Endpoint 0 This bit is reserved.</i>                                                                                                     |   |
| [3:2] | EP2_R_RES[1:0] | RW | The receiver at endpoint 2 controls the response to an OUT transaction:<br>00: Data ready and expects ACK;<br>01: Answer NYET;<br>10: Response NAK or busy;<br>11: Answer STALL or error.<br>Not valid for real-time/synchronous transfers.                   | 0 |
| [1:0] | EP2_T_RES[1:0] | RW | Endpoint 2 transmitter response control bits for IN transactions<br>00: Expect an answer ACK;<br>01: Expect an answer NYET;<br>10: Expect an answer NAK or busy;<br>11: Expect an answer STALL or error.<br>Not valid for real-time/synchronous transmission. | 0 |

#### 18.2.2.15 Endpoint 3 Transmit Length and Control Registers (R32\_UEP3\_CTRL)

| Bit     | Name            |
|---------|-----------------|
| [31:16] | R16_UEP3_CTRL_H |
| [15:0]  | R16_UEP3_TX_LEN |

#### 18.2.2.16 Endpoint 3 Transmit Length Register (R16\_UEP3\_TX\_LEN)

| Bit    | Name      | Access | Description                                    | Reset value |
|--------|-----------|--------|------------------------------------------------|-------------|
| [15:7] | Reserved  | RO     | Reserved.                                      | 0           |
| [6:0]  | EP0_T_LEN | RW     | The number of bytes transmitted by endpoint 3. | 0           |

#### 18.2.2.17 Endpoint 3 Control Register (R16\_UEP3\_CTRL\_H)

| Bit    | Name      | Access | Description                                                                                                                                                                             | Reset value |
|--------|-----------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [15:8] | Reserved  | RO     | Reserved.                                                                                                                                                                               | 0           |
| 7      | EP3_R_TOG | RW     | Sync trigger bits prepared by the receiver of USB endpoint 3 (Processing OUT transactions):<br>1: Expects DATA1;<br>0: Expects DATA0.<br>Not valid for real-time/synchronous transfers. | 0           |
| 6      | EP3_T_TOG | RW     | Sync trigger bits prepared by the sender of USB endpoint 3 (Handling IN transactions):<br>1: Transmit DATA1;                                                                            | 0           |

|       |                |    |                                                                                                                                                                                                                                                               |   |
|-------|----------------|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
|       |                |    | 0: Transmit DATA0.                                                                                                                                                                                                                                            |   |
| 5     | Reserved       | RO | Reserved.                                                                                                                                                                                                                                                     | 0 |
| 4     | EP3_TOG_AUTO   | RW | Synchronization Trigger Bit Auto Flip Enable Control Bit:<br>1: Auto flip after successful data sending and receiving;<br>0: Not auto-flip, can be switched manually.<br><i>Note: Endpoint 0 This bit is reserved.</i>                                        | 0 |

### 18.2.3 USB Host Register Description

In USB host mode, the chip provides a set of bi-directional host endpoints, including a transmit endpoint OUT and a receive endpoint IN. The maximum length of a packet is 1024 bytes (Simultaneous transfers), supporting control transfers, interrupt transfers, bulk transfers and real-time/synchronous transfers.

The RB\_UIF\_TRANSFER interrupt flag is always automatically set at the end of processing for each USB transaction initiated by the host endpoint. The application can query directly or in the USB interrupt service program and analyze the interrupt flag register R8\_USB\_INT\_FG to process each interrupt flag accordingly; and, if RB\_UIF\_TRANSFER is valid, then it also needs to continue to analyze the USB interrupt status register R8\_USB\_INT\_ST, based on the current USB transfer. If RB\_UIF\_TRANSFER is valid, then the USB interrupt status register R8\_USB\_INT\_ST should be analyzed further and processed accordingly according to the current USB transfer transaction's answer PID identification MASK\_UIS\_H\_RES.

If the sync trigger bit (RB\_UH\_R\_TOG) of the IN transaction of the host receive endpoint is set in advance, then it can be judged by RB\_U\_TOG\_OK or RB\_UIS\_TOG\_OK whether the sync trigger bit of the currently received packet matches the sync trigger bit of the host receive endpoint, if the data is synchronous, then the data is valid; if the data is not synchronous, then the data should be discarded. After each USB transmit or receive interrupt is processed, the synchronization trigger bit of the corresponding host endpoint should be correctly modified to synchronize the next transmitted packet and to check whether the next received packet is synchronized; in addition, by setting RB\_UH\_T\_AUTO\_TOG and RB\_UH\_R\_AUTO\_TOG, the corresponding synchronization trigger bit can be automatically flipped after a successful transmit or receive. synchronization trigger bits.

The USB host token setting register R8\_UH\_EP\_PID is used to set the endpoint number of the target device being operated and the token PID packet identification for this USB transmission transaction. The data corresponding to the SETUP token and OUT token is provided by the host transmit endpoint, the data ready to be sent is in the R16\_UH\_TX\_DMA buffer, the length of the data ready to be sent is set in the R16. The data corresponding to the IN token is returned by the target device to the host receiving endpoint, the received data is stored in the R16\_UH\_RX\_DMA buffer, and the received data length is stored in R16\_USB\_RX\_LEN.

Table 18-4 Host-related registers list

| Name            | Access address | Description                                 | Reset value |
|-----------------|----------------|---------------------------------------------|-------------|
| R8_HOST_CTRL    | 0x40023401     | USB host physical port control register     | 0xX0        |
| R8_HOST_EP_MOD  | 0x4002340D     | USB host endpoint mode control register     | 0x00        |
| R16_HOST_RX_DMA | 0x40023418     | USB host receive buffer start address       | 0xXXXX      |
| R16_HOST_TX_DMA | 0x4002341C     | USB host transmit buffer start address      | 0xXXXX      |
| R8_HOST_SETUP   | 0x40023426     | USB host auxiliary setup register           | 0x00        |
| R8_HOST_EP_PID  | 0x40023428     | USB host token setup register               | 0x00        |
| R8_HOST_RX_CTRL | 0x4002342A     | USB host receive endpoint control register  | 0x00        |
| R8_HOST_TX_LEN  | 0x4002342C     | USB host transmit length register           | 0xXX        |
| R8_HOST_TX_CTRL | 0x4002342E     | USB host transmit endpoint control register | 0x00        |

### 18.2.3.1 USB Host Control Register (R8\_HOST\_CTRL)

| Bit | Name            | Access | Description                                                                                                                                                                                                                                                                                                             | Reset value |

### 18.2.3.2 USB Host Endpoint Mode Control Register (R8\_HOST\_EP\_MOD)

| Bit   | Name              | Access | Description                                                                                                                    | Reset value |
|-------|-------------------|--------|--------------------------------------------------------------------------------------------------------------------------------|-------------|
| 7     | Reserved          | RO     | Reserved.                                                                                                                      | 0           |
| 6     | RB_UH_EP_TX_EN    | RW     | Host sends endpoint transmit (SETUP/OUT) enable bits:<br>1: Enable endpoint transmission;<br>0: Disable endpoint transmission. | 0           |
| 5     | Reserved          | RO     | Reserved.                                                                                                                      | 0           |
| 4     | RB_UH_EP_TBUF_MOD | RW     | Host transmit endpoint transmit data buffer mode control bit.                                                                  | 0           |
| 3     | RB_UH_EP_RX_EN    | RW     | Host receive endpoint receive (IN) enable bit:<br>1: Enable endpoint reception;<br>0: Disable endpoint reception.              | 0           |
| [2:1] | Reserved          | RO     | Reserved.                                                                                                                      | 00b         |
| 0     | RB_UH_EP_RBUF_MOD | RW     | USB host receive endpoint receive data buffer mode control bit.                                                                | 0           |

The host transmit endpoint data buffer mode is controlled by a combination of RB\_UH\_EP\_TX\_EN and RB\_UH\_EP\_TBUF\_MOD, refer to the table below.

Table 18-5 Host transmit buffer mode

| RB_UH_EP_TX_EN | RB_UH_EP_TBUF_MOD | Description: R16_UH_TX_DMA as starting address                                                                                                                               |
|----------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | X                 | Endpoint is disabled and the R16_UH_TX_DMA buffer is not used.                                                                                                               |
| 1              | 0                 | Single 64-byte transmit buffer (SETUP/OUT)                                                                                                                                   |
| 1              | 1                 | Double 64-byte transmit buffer, selected via RB_UH_T_TOG:<br>Selection of the first 64-byte buffer when RB_UH_T_TOG = 0;<br>Back 64-byte buffer selected when RB_UH_T_TOG=1. |

The host receive endpoint data buffer mode is controlled by the combination of RB\_UH\_EP\_RX\_EN and RB\_UH\_EP\_RBUF\_MOD, refer to the table below.

Table 18-6 Host receive buffer mode

| RB_UH_EP_RX_EN | RB_UH_EP_RBUF_MOD | Structure description: R16_UH_RX_DMA as starting address       |
|----------------|-------------------|----------------------------------------------------------------|
| 0              | X                 | Endpoint is disabled and the R16_UH_RX_DMA buffer is not used. |
| 1              | 0                 | Single 64-byte receive buffer (IN).                            |
| 1              | 1                 | Double 64-byte receive buffer, selected via                    |

|  |  |                                                                                                                                          |

### 18.2.3.3 USB Host Receive Buffer Start Address (R16\_HOST\_RX\_DMA)

| Bit    | Name          | Access | Description                                                                                                                    | Reset value |
|--------|---------------|--------|--------------------------------------------------------------------------------------------------------------------------------|-------------|
| [15:0] | R16_UH_RX_DMA | RW     | Start address of the host endpoint data receive buffer.<br>The lower 15 bits are valid and the address must be 4-byte aligned. | 0XXXXX      |

### 18.2.3.4 USB Host Transmit Buffer Start Address (R16\_HOST\_TX\_DMA)

| Bit    | Name          | Access | Description                                                                                                                     | Reset value |
|--------|---------------|--------|---------------------------------------------------------------------------------------------------------------------------------|-------------|
| [15:0] | R16_UH_TX_DMA | RW     | Start address of the host endpoint data transmit buffer.<br>The lower 15 bits are valid and the address must be 4-byte aligned. | 0XXXXX      |

### 18.2.3.5 USB Host Auxiliary Setup Register (R8\_HOST\_SETUP)

| Bit   | Name             | Access | Description                                                                                                                                                         | Reset value |
|-------|------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 7     | RB_UH_PRE_PID_EN | RW     | Low-speed leading packet PRE PID enable bit:<br>1: Enabled for communication with low-speed USB devices via the external HUB.<br>0: Disable the low-speed preamble. | 0           |
| 6     | RB_UH_SOF_EN     | RW     | Automatic SOF packet generation enable bit:<br>1: The host automatically generates SOF packets;<br>0: Not automatically generated, but can be generated manually.   | 0           |
| [5:0] | Reserved         | RO     | Reserved.                                                                                                                                                           | 000000b     |

### 18.2.3.6 USB Host Token Setup Register (R8\_HOST\_EP\_PID)

| Bit   | Name          | Access | Description                                                               | Reset value |
|-------|---------------|--------|---------------------------------------------------------------------------|-------------|
| [7:4] | MASK_UH_TOKEN | RW     | Set the token PID packet identifier for this USB transfer transaction.    | 0000b       |
| [3:0] | MASK_UH_ENDP  | RW     | Set the endpoint number of the target device being operated on this time. | 0000b       |

### 18.2.3.7 USB Host Receive Endpoint Control Register (R8\_HOST\_RX\_CTRL)

| Bit   | Name             | Access | Description                                                                                                                                                                                                                 | Reset value |
|-------|------------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 7     | RB_UH_R_TOG      | RW     | Desired synchronization trigger bits for USB host receivers (Handling IN transactions):<br>1: Expect DATA1;<br>0: Expect DATA0.                                                                                             | 0           |
| [6:5] | Reserved         | RO     | Reserved.                                                                                                                                                                                                                   | 00b         |
| 4     | RB_UH_R_AUTO_TOG | RW     | Sync trigger bit auto-flip enable control bit:<br>1: Automatically flips the corresponding desired sync trigger bit (RB_UH_R_TOG) upon successful data reception;<br>0: Not automatically flipped, can be manually toggled. | 0           |
| 3     | Reserved         | RO     | Reserved.                                                                                                                                                                                                                   | 0           |
| 2     | RB_UH_R_RES      | RW     | Control bits for host receiver response to IN transactions:<br>1: No response, for real-time/synchronous transmission of non-zero endpoints;<br>0: Answer to ACK.                                                           | 0           |
| [1:0] | Reserved         | RO     | Reserved.                                                                                                                                                                                                                   | 00b         |

#### 18.2.3.8 USB Host Transmit Length Register (R8\_HOST\_TX\_LEN)

| Bit   | Name         | Access | Description                                                                               | Reset value |
|-------|--------------|--------|-------------------------------------------------------------------------------------------|-------------|
| [7:0] | R8_UH_TX_LEN | RW     | Sets the number of bytes of data that the USB host sending endpoint is ready to transmit. | 0xXX        |

#### 18.2.3.9 USB Host Transmit Endpoint Control Register (R8\_HOST\_TX\_CTRL)

| Bit | Name             | Access | Description                                                                                                                                                                                                                                | Reset value |
|-----|------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 7   | Reserved         | RO     | Reserved.                                                                                                                                                                                                                                  | 0           |
| 6   | RB_UH_T_TOG      | RW     | Sync trigger bits prepared by the USB host sender (Which handles SETUP/OUT transactions):<br>1: Indicates that DATA1 is sent;<br>0: Indicates that DATA0 is sent.                                                                          | 0           |
| 5   | Reserved         | RO     | Reserved.                                                                                                                                                                                                                                  | 0           |
| 4   | RB_UH_T_AUTO_TOG | RW     | Synchronous trigger bit auto-flip enable control bit:<br>1: The corresponding synchronous trigger bit (RB_UH_T_TOG) is automatically flipped upon successful data transmission;<br>0: Not automatically flipped, can be switched manually. | 0           |

|       |             |    |                                                                                                                                                                                           |      |
|-------|-------------|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| [3:1] | Reserved    | RO | Reserved.                                                                                                                                                                                 | 000b |
| 0     | RB_UH_T_RES | RW | USB host transmitter response control bits for SETUP/OUT transactions:<br>1: No response expected, for real-time/synchronous transmission of non-0 endpoints;<br>0: Expect an answer ACK. | 0    |

*Note: The duration of the reset is determined by the duration of the RB\_UH\_TX\_BUS\_RST high (At least 10ms is recommended, wait a few us after the end of the reset and you can query the speed type directly). If the host wakes up the device, the hardware automatically sends a 30ms wake-up signal (K) after bUH\_TX\_BUS\_RESUME is pulled high. bUH\_TX\_BUS\_RESUME needs to be cleared manually to avoid affecting the next host hang-up (bUH\_TX\_BUS\_RESUME is maintained high for at least 50ns).*

## Chapter 19 Electronic Signature (ESIG)

The electronic signature contains chip identification information: The capacity of the flash memory area and the unique identification. It is programmed into the system storage area of the memory module by the manufacturer at the factory, and can be read by SWD (SDI) or application code.

### 19.1 Functional Description

Flash memory area capacity: Indicates the available size of the current chip user application program.

Unique ID: 96-bit binary code, unique to any microcontroller; users can only read and access but cannot modify it. This unique identification information can be used as the security password, encryption key, product serial number, etc. of the microcontroller (Product) to improve the system security mechanism or indicate identity information.

Users of the above content can conduct read access according to 8/16/32 bits.

### 19.2 Register Description

Table 19-1 ESIG registers

| Name            | Access address | Description             | Reset value |
|-----------------|----------------|-------------------------|-------------|
| R16_ESIG_FLACAP | 0x1FFFF7E0     | Flash capacity register | 0XXXXX      |
| R32_ESIG_UNIID1 | 0x1FFFF7E8     | UID register 1          | 0XXXXXXXXX  |
| R32_ESIG_UNIID2 | 0x1FFFF7EC     | UID register 2          | 0XXXXXXXXX  |
| R32_ESIG_UNIID3 | 0x1FFFF7F0     | UID register 3          | 0XXXXXXXXX  |

#### 19.2.1 Flash Capacity Register (ESIG\_FLACAP)

| Bit    | Name   | Access | Description                                                    | Reset value |
|--------|--------|--------|----------------------------------------------------------------|-------------|
| [15:0] | F_SIZE | RO     | Flash memory capacity in Kbyte.<br>Example: 0x0080 = 128Kbytes | X           |

#### 19.2.2 UID Register (ESIG\_UNIID1)

| Bit    | Name       | Access | Description      | Reset value |
|--------|------------|--------|------------------|-------------|
| [31:0] | U_ID[31:0] | RO     | UID's bits 0-31. | X           |

### 19.2.3 UID Register (ESIG\_UNIID2)

| Bit    | Name        | Access | Description       | Reset value |
|--------|-------------|--------|-------------------|-------------|
| [31:0] | U_ID[63:32] | RO     | UID's bits 32-63. | X           |

### 19.2.4 UID Register (ESIG\_UNIID3)

| Bit    | Name        | Access | Description       | Reset value |
|--------|-------------|--------|-------------------|-------------|
| [31:0] | U_ID[95:64] | RO     | UID's bits 64-95. | X           |

## Chapter 20 Flash Memory and User Option Bytes

### 20.1 Flash Memory Organization

The internal flash memory organization structure of the chip is as follows:

Table 20-1 Flash memory organization structure

| Block             | Name                            | Address Range             | Size(byte) |
|-------------------|---------------------------------|---------------------------|------------|
| Main memory       | Page 0                          | 0x0800 0000 – 0x0800 00FF | 256        |
|                   | Page 1                          | 0x0800 0100 – 0x0800 01FF | 256        |
|                   | Page 2                          | 0x0800 0200 – 0x0800 02FF | 256        |
|                   | Page 3                          | 0x0800 0300 – 0x0800 03FF | 256        |
|                   | ...                             | ...                       | ...        |
|                   | Page 247                        | 0x0800 F700– 0x0800 F7FF  | 256        |
| Information block | Launcher code                   | 0x1FFF 0000 – 0x1FFF 0CFF | 3K+256     |
|                   | User option byte                | 0x1FFF F800 – 0x1FFF F8FF | 256        |
|                   | Manufacturer configuration word | 0x1FFF F700 – 0x1FFF F7FF | 256        |

Notes:

1) The main memory area above is used for user's application storage and is write-protected in 2K byte (8 pages) units;

All areas are user-operable under certain conditions, except for the "vendor configuration word" area, which is factory locked and inaccessible to the user.

### 20.2 Flash Memory Programming and Safety

#### 20.2.1 Program/Erase Methods

- Fast programming: this method uses the page operation method (Recommended). After a specific sequence of unlocking, a single 256 byte programming and 256 byte erasure, 1K byte erasure and whole chip erasure are performed.

#### 20.2.2 Security - Protection against Illegal Access (Read, write, erase)

- Page write protection
- Read protection

Under the read protection state:

- 1) The main memory pages 0-7 (2K bytes) are automatically write-protected and are not controlled by the FLASH\_WPR register; when the read protection status is released, all main memory pages will be controlled by the FLASH\_WPR register.
- 2) The main memory cannot be erased or programmed in the system boot code area, SWD or SDI mode, and RAM area, except for the entire chip erasure. User-selected word area can be erased or programmed. If you try to release the read protection (Program user word), the chip will automatically erase the entire user area

Note: When programming/erasing operations of flash memory are made, the internal RC oscillator (HSI) must be switched on.

## 20.3 Register Description

Table 20-2 FLASH registers

| Name               | Access address | Description               | Reset value |
|--------------------|----------------|---------------------------|-------------|
| R32_FLASH_ACTLR    | 0x40022000     | Control register          | 0x00000000  |
| R32_FLASH_KEYR     | 0x40022004     | FPEC key register         | 0xFFFFFFFF  |
| R32_FLASH_OBKEYR   | 0x40022008     | OBKEY register            | 0xFFFFFFFF  |
| R32_FLASH_STATR    | 0x4002200C     | Status register           | 0x0000B000  |
| R32_FLASH_CTLR     | 0x40022010     | Configuration register    | 0x00008080  |
| R32_FLASH_ADDR     | 0x40022014     | Address register          | 0x00000000  |
| R32_FLASH_OBR      | 0x4002201C     | Selection word register   | 0xFFFFFFFF  |
| R32_FLASH_WPR      | 0x40022020     | Write protection register | 0xFFFFFFFF  |
| R32_FLASH_MODEKEYR | 0x40022024     | Extension key register    | 0xFFFFFFFF  |
| R32_BOOT_MODEKEYR  | 0x40022028     | Unlock BOOT key register  | 0xFFFFFFFF  |

### 20.3.1 Access Control Register (FLASH\_ACTLR)

Offset address: 0x00

| Bit    | Name         | Access | Description                                                                                                                                | Reset value |
|--------|--------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [31:2] | Reserved     | RO     | Reserved.                                                                                                                                  | 0           |
| [1:0]  | LATENCY[1:0] | RW     | FLASH wait state count:<br>00: 0 wait (HCLK<=12MHz);<br>01: 1 wait (12MHz<HCLK<=24MHz);<br>10: 2 wait (24MHz<HCLK<=48MHz);<br>11: Invalid. | 0           |

### 20.3.2 FPEC Key Register (FLASH\_KEYR)

Offset address: 0x04

| Bit    | Name       | Access | Description                                       | Reset value |
|--------|------------|--------|---------------------------------------------------|-------------|
| [31:0] | KEYR[31:0] | WO     | FPEC keys, unlock keys for entering FPEC include: | X           |

|  |  |  |                                          |  |
|--|--|--|------------------------------------------|--|
|  |  |  | KEY1 = 0x45670123;<br>KEY2 = 0xCDEF89AB. |  |
|--|--|--|------------------------------------------|--|

### 20.3.3 OBKEY Register (FLASH\_OBKEYR)

Offset address: 0x08

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| OBKEYR[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| OBKEYR[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| Bit    | Name         | Access | Description                                                                                                                                                 | Reset value |
|--------|--------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [31:0] | OBKEYR[31:0] | WO     | Select word key for entering the select word key to unlock OPTWRE.<br>KEY1 = 0x45670123;<br>KEY2 = 0xCDEF89AB.<br><i>(Note: Need to unlock FLASH first)</i> | X           |

### 20.3.4 Status Register (FLASH\_STATR)

Offset address: 0x0C

| Bit    | Name           | Access | Description                                                                                      | Reset value |
|--------|----------------|--------|--------------------------------------------------------------------------------------------------|-------------|
| [31:0] | MODEKEYR[31:0] | WO     | Enter the following sequence to unlock the BOOT area<br>KEY1 = 0x45670123;<br>KEY2 = 0xCDEF89AB. | X           |

## 20.4 Flash Operation Procedure

### 20.4.1 Read Operation

Direct addressing is in the general address space, and the user can access the content of the flash memory module and get the corresponding data through any read operation of 8/16/32-bit data.

### 20.4.2 Unlock Flash Memory

After the system reset, the flash memory controller (FPEC) and FLASH\_CTLR register will be locked and cannot be accessed. The flash memory controller module can be unlocked by writing the sequence to the FLASH\_KEYR

register.

Unlock sequence:

- 1) Write KEY1 = 0x45670123 to the FLASH\_KEYR register (Must operate KEY1 first);
- 2) Write KEY2 = 0xCDEF89AB to the FLASH\_KEYR register (Must operate KEY2 secondly).

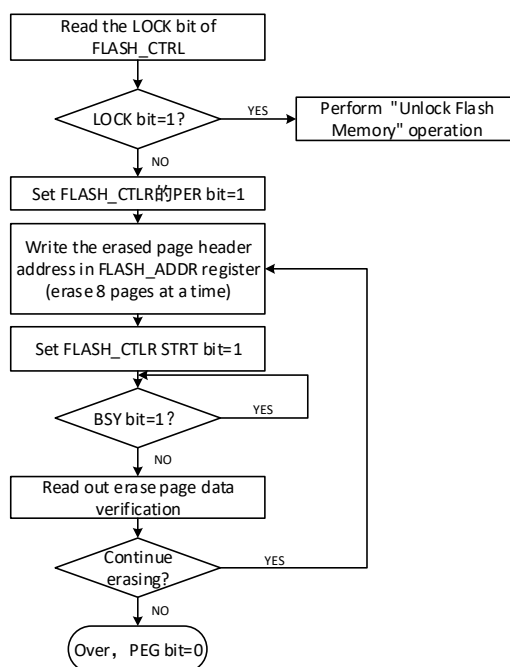

The above operations must be performed sequentially and continuously. Otherwise, it is an error operation, which will lock the FPEC module and FLASH\_CTLR register and generate a bus error until the next system reset.

The flash memory controller (FPEC) and the FLASH\_CTLR register can be locked again by setting the "LOCK" bit in the FLASH\_CTLR register to 1.

### 20.4.3 Main Memory Standard Erase

Flash memory can be erased by standard page (1K bytes) or by whole chip.

Figure 20-2 FLASH page erase

- 1) Check the LOCK bit of FLASH\_CTLR register, if it is 1, you need to perform the "Unlock Flash" operation.
- 2) Set the PER bit of FLASH\_CTLR register to '1' to enable the standard page erase mode.
- 3) Write the page header address to the FLASH\_ADDR register to select the page to be erased.
- 4) Set the STRT bit of FLASH\_CTLR register to '1' to initiate an erase action.
- 5) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to become '1' to indicate the end of erasure, and clear the EOP bit to 0.
- 6) Read the data of the erased page for verification.
- 7) Continue the standard page erase can repeat steps 3-5, end the erase to clear the PEG bit to 0.

*Note: After successful erasure, the word reads - 0xFF.*

Figure 20-3 FLASH whole chip erase

- 1) Check the LOCK bit of FLASH\_CTRL register, if it is 1, you need to perform the "unlock flash memory" operation.
- 2) Set the MER bit of FLASH\_CTRL register to '1' to enable the whole chip erase mode.
- 3) Set the STAT bit of FLASH\_CTRL register to '1' to start the erase operation.
- 4) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to be '1' to indicate the end of erasure, and clear the EOP bit to 0.
- 5) Read the data of the erased page for verification.
- 6) Clear the MER bit to 0.

#### 20.4.4 Fast Programming Mode Unlock

Fast programming mode operation can be unlocked by writing a sequence to the FLASH\_MODEKEYR register. After unlocking, the FLOCK bit in the FLASH\_CTRL register will clear to 0, indicating that fast erase and programming operations can be performed. The FLASH\_CTRL register can be locked again by software setting the "FLOCK" bit to 1.

Unlock sequence:

- 1) Write KEY1 = 0x45670123 to the FLASH\_MODEKEYR register;
- 2) Write KEY2 = 0xCDEF89AB to the FLASH\_MODEKEYR register.

The above operations must be performed sequentially and consecutively, otherwise they will be locked as errors and cannot be unlocked until the next system reset.

*Note: The fast programming operation needs to unlock the "LOCK" and "FLOCK" layers.*

#### 20.4.5 Main Memory Fast Programming

Fast programming is done on a page by page basis (256 bytes).

- 1) Check the FLASH\_CTRL register LOCK bit, if it is '1', you need to perform the "Unlock Flash Memory" operation.
- 2) Check the FLASH\_CTRL register FLOCK bit, if it is '1', you need to perform the "Fast Programming Mode Unlock" operation.
- 3) Check the BSY bit of the FLASH\_STATR register to make sure there is no other programming operation in progress.
- 4) Set the FTPG bit of FLASH\_CTRL register to '1' to enable fast page programming mode.
- 5) Set the BUFRST bit of the FLASH\_CTRL register to perform a clear internal 256 byte buffer operation.

- 6) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to become '1' to indicate the end of clearing, and clear the EOP bit to 0
- 7) Write data to the FLASH address using the 32-bit method, e.g.  

```
*(uint32_t*) 0x80000000 = 0x12345678;
```
- 8) Then set the BUFLOAD bit of the FLASH\_CTLR register and execute the load into the buffer.
- 9) Wait for WR\_BSY of FLASH\_STATR register to be '0' and write the next data.
- 10) Repeat steps 7-9 a total of 64 times to load all 16 bytes of data into the cache (the main 4 rounds of operation addresses should be consecutive).
- 11) Write the first address of the fast programming page to the FLASH\_ADDR register.
- 12) Set the STRT bit of the FLASH\_CTLR register to '1' to start fast page programming.
- 13) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to become '1' to indicate the completion of one fast page programming and clear the EOP bit to 0.
- 14) Query the FLASH\_STATR register to see if there is an error or read the programmed address data checksum.
- 15) Continue fast page programming by repeating steps 5-14 and end programming by clearing the FTPG bit to 0.

### 20.4.6 Main Memory Fast Erase

Fast erase is performed by page (256 bytes).

- 1) Check the LOCK bit of FLASH\_CTLR register, if it is 1, you need to perform the "Unlock Flash Memory" operation.
- 2) Check the FLASH\_CTLR register FLOCK bit, if it is 1, you need to perform the "fast programming mode unlock" operation.
- 3) Check the BSY bit of FLASH\_STATR register to make sure there is no other programming operation in progress.
- 4) Set the FTER bit of FLASH\_CTLR register to '1' to enable the fast page erase (256 bytes) mode function.
- 5) Write the first address of the fast erase page to the FLASH\_ADDR register.
- 6) Set the STRT bit of FLASH\_CTLR register to '1' to start a fast page erase (256 bytes) action.
- 7) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to become '1' to indicate the end of erase, and clear the EOP bit to 0.
- 8) Query the FLASH\_STATR register to see if there is an error or read the erase page address data checksum.
- 9) Continue fast page erase can repeat steps 5-8, end erase to clear the FTER bit to 0.

*Note: After a successful erase, the word reads - 0xFF.*

Fast erase is performed by block (32K bytes).

- 1) Check the FLASH\_CTLR register LOCK bit, if it is 1, you need to perform the "Unlock Flash" operation.
- 2) Check the FLASH\_CTLR register FLOCK bit, if it is 1, you need to perform the "fast programming mode unlock" operation.
- 3) Check the BSY bit of FLASH\_STATR register to make sure there is no other programming operation in progress.
- 4) Set the BER32 bit of FLASH\_CTLR register to '1' to enable the fast block erase (32K bytes) mode function.
- 5) Write the first address of the fast erase block to the FLASH\_ADDR register.
- 6) Set the STRT bit of FLASH\_CTLR register to '1' to initiate a fast block erase (32K bytes) action.
- 7) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to become '1' to indicate the end of erase, and clear the EOP bit to 0.
- 8) Query the FLASH\_STATR register to see if there is an error or read the erase page address data checksum.
- 9) Continue fast page erase can repeat steps 5-8, end erase to clear the BER32 bit to 0.

*Note: After a successful erase, the word read - 0xFF.*

## 20.5 User Option Bytes

The user option byte is solidified in FLASH and is reloaded into the corresponding register after a system reset, and can be erased and programmed by the user at will. The user option byte information block has a total of 8 bytes (4 bytes for write protection, 1 byte for read protection, 1 byte for configuration options and 2 bytes for user data) and each bit has its own inverse code bit for verification during loading. The structure and meaning of the option byte information is described below.

Table 20-3 32-bit option byte format division

| [31:24]                        | [23:16]        | [15:8]                         | [7:0]          |
|--------------------------------|----------------|--------------------------------|----------------|
| Inverse code of option bytes 1 | Option bytes 1 | Inverse code of option bytes 0 | Option bytes 0 |

Table 20-4 User option bytes information structure

| Address<br>Bit | [31:24] | [23:16] | [15:8] | [7:0] |
|----------------|---------|---------|--------|-------|
| 0x1FFFF800     | nUSER   | USER    | nRDPR  | RDPR  |
| 0x1FFFF804     | nData1  | Data1   | nData0 | Data0 |
| 0x1FFFF808     | nWRPR1  | WRPR1   | nWRPR0 | WRPR0 |
| 0x1FFFF80C     | nWRPR3  | WRPR3   | nWRPR2 | WRPR2 |

| Name/Byte |         | Description                                                                                                                                                                                                                                                                                                                                                                       | Reset value                                                                                                                                                                                                                          |     |

### 20.5.1 User Option Bytes Unlock

The user option bytes operation can be unlocked by writing the sequence to the FLASH\_OBKEYR register. After unlocking, the OBWRE bit in the FLASH\_CTLR register will be set to 1, indicating that user option bytes can be erased and programmed. By setting the OBWRE bit in the FLASH\_CTLR register, it will be cleared to 0 by software to lock again.

Unlocking sequence

- 1) Write KEY1 = 0x45670123 to the FLASH\_OBKEYR register;
- 2) Write KEY2 = 0xCDEF89AB to the FLASH\_OBKEYR register.

*Note: The user needs to unlock the 2 layers: "LOCK" and "OBWRE" for byte option.*

### 20.5.2 User Option Bytes Programming

- 1) Check the LOCK bit of FLASH\_CTLR register, if it is '1', you need to perform the operation of "Unlock Flash Memory".
- 2) Check the FLASH\_CTLR register FLOCK bit, if it is '1', you need to perform the "Fast Programming Mode Unlock" operation.
- 3) Check the BSY bit of the FLASH\_STATR register to make sure there is no other programming operation in progress.
- 4) Set the FTPG bit of FLASH\_CTLR register to '1' to enable fast page programming mode.
- 5) Set the BUFRST bit of the FLASH\_CTLR register to perform a clear internal 256 byte buffer operation.
- 6) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to become '1' to indicate the end of clearing, and clear the EOP bit to 0
- 7) Write data to the FLASH address using the 32-bit method, e.g.

```
*(uint32_t*) 0x1FFFF804= 0x5AA55AA5;
```

- 8) Then set the BUFLOAD bit of the FLASH\_CTLR register to perform a load into the buffer.
  - 9) Wait for WR\_BSY of FLASH\_STATR register to be '0' and write the next data.
  - 10) Repeat steps 5-9 a total of 4 times to load all 256 bytes of data into the cache (The main 16 rounds of operation addresses should be consecutive).
  - 11) Write the first address of the fast programming page to the FLASH\_ADDR register.
  - 12) Set the STRT bit of the FLASH\_CTLR register to '1' to start fast page programming.
  - 13) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to become '1' to indicate the completion of one fast page programming and clear the EOP bit to 0.
  - 14) Query the FLASH\_STATR register to see if there is an error or read the programmed address data checksum.
  - 15) Continue fast page programming you can repeat steps 5-14 and end programming to clear the FTPG bit to 0.
- Note: When the "Read Protected" in the Modify Selection Word becomes "Unprotected", a whole chip erase of the main memory will be performed automatically. If a selection other than "Read Protected" is modified, a full erase operation will not occur.*

### 20.5.3 User Option Bytes Erase

Directly erase the entire 256-byte user option byte area.

- 1) Check the LOCK bit in the FLASH\_CTLR register, if it is 1, the "Unlock Flash" operation needs to be performed.
- 2) Check the BSY bit of the FLASH\_STATR register to confirm that there is no programming operation in progress.
- 3) Check the OBWRE bit of FLASH\_CTLR register, if it is 0, you need to perform the "User Option Byte Unlock" operation.
- 4) Set the OBER bit of FLASH\_CTLR register to '1', then set the STRT bit of FLASH\_CTLR register to '1' to enable user option byte erase.
- 5) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to be '1' to indicate the end of erasure, and clear the EOP bit to 0
- 6) Read the erase address data checksum.
- 7) End to clear the OBER bit to 0.

*Note: After successful erasure, word read - 0xFF.*

### 20.5.4 Release Read Protection

Whether the flash is read protected or not is determined by the user option byte. Reading the FLASH\_OBR register, when the RDPRT bit is '1' indicates that the flash is currently in a read protected state and the flash is operationally protected by a series of security guards in the read protected state. The process of unprotecting a read is as follows:

- 1) Erase the entire user option byte area, at which point the read protection field RDPR, at which point the read protection is still in effect.
- 2) Program the user option byte to write the correct RDPR code 0xA5 to unprotect the flash memory from read protection. (This step will first cause the system to automatically perform an entire erase operation on the flash memory)
- 3) Perform a power-on reset to reload the option byte (including the new RDPR code), at which point the read protection is removed.

### 20.5.5 Release Write Protection

Whether the flash memory is write-protected or not is determined by the user option byte. Read the FLASH\_WPR register, each bit represents 2K bytes of flash space, when the bit is '1' it means non-write protected status, when it is '0' it means write protected. The process of unwrite-protecting is as follows:

- 1) Erase the entire user option byte area.
- 2) Write the correct RDPR code 0xA5 to allow read access;
- 3) Perform a system reset, reload the option byte (including the new WRPR[3:0] byte) and the write protection is removed.

## Chapter 21 USB PD Controller (USB PD)

### 21.1 Introduction to USB PD Controller

The chip has built-in USB Power Delivery controller and PD transceiver PHY, supports USB type-C master-slave detection, automatic BMC codec and CRC, hardware edge control, supports USB PD2.0 and PD3.0 power transmission control, supports fast charging, supports UFP/DFP and PDUSB, and supports PD power receiving and PD power supply applications.

- Built-in USB type-C interface, master/slave detection support, DRP, Sink/Consumer and Source/Provider support;
- Built-in USB PD transceiver PHY with integrated hardware edge-slope control;
- Built-in USB Power Delivery controller, automatic BMC codec, 4b5b codec and CRC;
- Support SOP, SOP', SOP'' PD packets and USB PD reset signal frame hardware reset;
- Support maximum packet length of 510 bytes, DMA;
- Support USB PD 2.0 and 3.0 power transfer protocols, USB port supports BC and other charging protocols.

### 21.2 Register Description

Table 21-1 USB PD-related registers

| Name              | Access address | Description                        | Reset value |
|-------------------|----------------|------------------------------------|-------------|
| R32_USBPD_CONFIG  | 0x40027000     | PD configuration register          | 0x00000002  |
| R16_CONFIG        | 0x40027000     | PD interrupt enable register       | 0x0002      |
| R16_BMC_CLK_CNT   | 0x40027002     | BMC sample clock counter           | 0x0000      |
| R32_USBPD_CONTROL | 0x40027004     | PD control register                | 0x00000000  |

## Chapter 22 Programmable Protocol I/O Microcontroller (PIOC)

The CH643 is embedded with a programmable protocol I/O microcontroller based on a single clock cycle dedicated lean instruction set RISC core running at system mains frequency with 2K instruction program ROM and 49 SFR registers and PWM timer/counter, supporting protocol control of 2 I/O pins.

### 22.1 Main Features

- RISC core, optimized single cycle bit manipulation instruction set, fully static design.
- Multiplex 4K bytes of system SRAM as 2K capacity program ROM, supports program pause and dynamic loading.
- Provide 33 bytes of 1 register each in bidirectional and unidirectional mode, providing 6 levels of independent stacking.
- Support 2 general-purpose bi-directional I/O protocol controls and input level change detection.
- Support 1- and 2-wire interfaces with multiple protocol specifications by dynamically loading different protocol programs.

### 22.2 Applications

A wide range of protocol specification target programs are available, dynamically loaded to support the corresponding 1- and 2-wire interfaces.

## Chapter 23 Debug Support

### 23.1 Main Features

This register allows the MCU to be configured in the debug state. includes

- Support counter of Independent Watchdog (IWDG)
- Support counter of Window Watchdog (WWDG)
- Support counter of Timer 1
- Support counter of Timer 2
- Support counter of Timer 3

### 23.2 Register Description

#### 23.2.1 Debug MCU Configuration Register (DBGMCU\_CR)

Address: 0x7C0(CSR)

| 2     | STANDBY  | RW | Debug the standby mode bits.<br>1: (HCLK on) The digital circuitry section is not powered down and the HCLK clock is clocked by the internal RL oscillator. Alternatively, the microcontroller exits STANDBY mode and reset by generating a system reset is the same;<br>0: (HCLK off) The entire digital circuitry section is powered down.<br>From a software point of view, exiting STANDBY mode is the same as a reset (Except that some status bits indicate that the microcontroller has just exited from the STANDBY state).                                                                                                  | 0 |
| 1     | STOP     | RW | Debug stop mode bit.<br>1: (HCLK on) When in stop mode, the HCLK clock is provided by the internal RC oscillator. When exiting stop mode, the software must reconfigure the clock system to start the PLL, crystal, etc. (Same operation as when this bit is configured to 0);<br>0: (HCLK off) When in STOP mode, the clock controller disables all clocks (Including HCLK). When exiting from STOP mode, the clock is configured as it was after the reset (The microcontroller is clocked by the internal RC oscillator (HSI)). Therefore, the software must reconfigure the clock control system to start the PLL, crystal, etc. | 0 |
| 0     | SLEEP    | RW | Debug sleep mode bits.<br>1: (HCLK on) In sleep mode, the HCLK clocks are all provided by the originally configured system clock;<br>0: (HCLK Off) In sleep mode, HCLK is provided by the originally configured system clock and HCLK is off. Since sleep mode does not reset the configured clock system, the software does not need to reconfigure the clock system when exiting from sleep mode.                                                                                                                                                                                                                                  | 0 |

## Chapter 24 Pulse Width Modulated LED Driver

### 24.1 Main Features

- 3\*16=48 channels PWM drive, support typical 8, 16, 18, up to 32 COM common end dynamic scan
- Fully built-in driver COM method supports 192 groups of RGB tri-color LEDs or 576 monochrome LEDs (8C\*3\*24)
- External PMOS driver COM method supports 288 RGB LEDs or 864 monochrome LEDs (16C\*3\*18)
- Optional 7-bit or 8-bit single-color PWM data, up to 3\*8-bit combined color PWM, supporting 16777216 combined colors
- Optional 6-bit or 7-bit or 8-bit luminance PWM data, support 256 levels of grayscale
- Multi-level adjustable fade time, support color PWM repeat group frame, support 1/2~1/18 or more COM dynamic scan
- Dedicated DMA mode, supports loading pre-set cured data from Flash-ROM or edited display data from RAM
- Support 16\*COM matrix keyboard scan detection in current mode, multiplexing LED driver pins to save I/O resources

The following is the RGB LED driver structure of CH643, which supports monochrome LEDs for reference only.

The CH643 can support both RGBLED matrix dynamic display drive and keyboard matrix scan detection, both LED matrix and keyboard matrix are driven by PWM channel pins as column, LED matrix supports up to 3\*16=48 columns and keyboard matrix supports up to 16 columns. In the LED column drive enable register LED\_PWM\_PIN\_\* to enable PWM as needed, each column corresponds to a group of RGB PWM, i.e. 3 PWM pins.

The LED row drive is dynamically scanned by the common terminal COM in a time-sharing manner. COM drive is divided into two ways: fully built-in way, referred to as internal drive; external PMOS way, referred to as external drive. COM can be enabled in the COM enable register LED\_COM\_E\_\* of each pin as needed, and any pin can be activated in the line drive COM selection register LED\_COM\_SEL.

The fully built-in method is peripherally streamlined and low-cost, with the COM pin internal NMOS directly driving the sink fill current as line scan, and the PWM channel is connected to the LED anode by the internal PMOS providing the source current. Usually the PA pin is used as PWM and the PB pin is used as COM.

The external PMOS approach supports higher current and higher brightness, with COM pins controlling external P-type MOSFETs to provide source current for line scan, and PWM channels from internal NMOS to provide sink source current to connect to the LED cathode. Usually PB pin as well as PA pin as PWM, PC pin and the remaining pins control the external P-type MOSFETs respectively.

In addition, there is a fully external drive based on the external PMOS method, COM pins control the external P-type MOSFET to provide source current for line scan, PWM pins control the external N-type MOSFET or NPN transistor to provide sink fill current to connect the LED cathode, respectively. The overall power is not limited to support higher brightness.

The keyboard matrix supports the same number of COM as the LED matrix as line scan output, fully built-in mode by PA0-15 series resistors as the current mode column sampling input, potting current is valid; external PMOS mode by PB0-15 series resistors as the current mode column sampling input, source current is valid. Current mode key detection reuses the LED display driver pins without additional GPIOs; the CH643 also supports regular voltage

mode key detection, using multiple additional GPIO pins as column sampling inputs.

All PA pins have simple constant current function for source current and simple constant current function for sink current; all PB pins have simple constant current function for sink current and large sink current driving capability as fully built-in COM driver.

The polarity of all PWM and COM output pins can be set by GPIOx\_OUTDR. 0 corresponds to the default low level when idle and high level when active; 1 corresponds to the default high level when idle and low level when active.

CH643 supports various application scenarios, mainly determined by COM drive mode and PWM pin mode, the detailed matrix combination is as follows.

| LED matrix         | PWM pin mode | PWM channel Pin name | PWM channel LED columns | Keyboard columns | COM number line scan | CH 643W | CH 643Q | CH 643L | CH 643U | COM method Peripherals |

## 24.2 Function Description

### 24.2.1 16-column RGB External Application (16C\*3\*X)

The PWM pin pattern for the 16-column RGB external driver application is PA24PB24.

Column drive is active low, driven by PA[23:0] and PB[23:0] with 48 PWM pins, each RGB tricolor LED corresponds to a group of 3 PWMs, totaling 16 columns. PA0/PA8/PA16 drive the 1st RGB column, and so on, PB7/PB15/PB23 drive the 16th RGB column.

The row drive is active high, which is achieved by multiple COM pins controlling external P-type MOSFETs respectively. No more than one COM pin is low at any moment, and the output is high after the external P-type MOSFETs are inverted.

Support 48 columns \* multiple COM monochrome LED display matrix, 16 columns \* multiple COM RGB tricolor LED display matrix, the number of rows that is the number of COM depends on the number of GPIOs available on the chip.

During initialization, the PWM pins used must be set to 1 in GPIOx\_OUTDR to set the output polarity to active low. The COM pins used must be set to 1 in GPIOx\_OUTDR to set the output polarity to active low.

When displaying, the luminance PWM (LED\_INTEN\_CNT) is the basic cycle and counts the LED clock cycle selected by CLK\_FREQ; the color PWM (LED\_COLOR\_CNT) counts the whole cycle of the luminance PWM; the combination of luminance PWM and color PWM realizes the superposition control of luminance and color. PWM\_REPEAT selects the number of repetitions in color PWM cycles during each line drive, when a line display is finished, the display pauses and enters interrupt.

During the interruption, if current mode key detection is required, the PKEY\_MODE bit of the LED\_KEY\_CTRL register can be turned on, which will automatically turn off the output of the PWM pin, enable the pull-up, and enable the source current detection circuit. If the input of any of the PB [15:0] pins is detected to be low, it means that the pin is pulled down by a COM (Usually the current COM), that is, the key is detected, and because only one of the multiple COM is low, the matrix positioning of the key can be achieved, and the PKEY\_MODE bit needs to be turned off after detection.

During the interruption, the next row of display data is loaded. Writing 16 to LED\_DMA\_CNT means that the DMA is required to load 16 32-bit data, and the corresponding PWM data is loaded to 16 groups of PWM in turn, and the LED\_DMA\_CNT is decreasing. The lower 8 bits of each 32-bit data is luminance PWM data, and the last 3 8-bit data are R, G, B tricolor data in turn. Writes a new COM pin to LED\_COM\_SEL and automatically clears the interrupt flag. When the LED\_DMA\_CNT is reduced to 0, the bit 0 of the LED\_COL\_OE register is set to 1 (The interrupt can be cleared automatically), the interrupt flag is cleared, and the blanking time is satisfied, the line display for the new COM pin starts, and then the interrupt is completed.

If 16 times continuous DMA affects other peripherals, it can also be divided into two times of DMA, each time LED\_DMA\_CNT setting 8.

PWM\_REPEAT is set to repeat several rounds of color PWM cycles in one PWM frame, that is, to implement several rounds of color PWM for a COM during the interval between two interrupts.

During the interruption, detect whether there are keys on the relevant PWM pins in the low-level state of a COM, load the PWM data of the new COM, and switch to the next COM. After all the COM cycles are completed, there will be a complete display cycle and keyboard scanning cycle.

During the interruption, the next row of display data is loaded. Writing 16 to LED\_DMA\_CNT means that the DMA is required to load 16 32-bit data, and the corresponding PWM data is loaded to 16 groups of PWM in turn, and the LED\_DMA\_CNT is decreasing. The lower 8 bits of each 32-bit data is luminance PWM data, and the last 3 8-bit data are R, G, B tricolor data in turn. Writes a new COM pin to LED\_COM\_SEL and automatically clears the interrupt flag. When the LED\_DMA\_CNT is reduced to 0, the bit 0 of the LED\_COL\_OE register is set to 1 (The interrupt can be cleared automatically), the interrupt flag is cleared, and the blanking time is satisfied, the line display for the new COM pin starts, and then the interrupt is completed.

If 16 times continuous DMA affects other peripherals, it can also be divided into two times of DMA, each time LED\_DMA\_CNT setting 8.

PWM\_REPEAT is set to repeat several rounds of color PWM cycles in one PWM frame, that is, to implement several rounds of color PWM for a COM during the interval between two interrupts.

During the interruption, detect whether there are keys on the relevant PWM pins in the low-level state of a COM, load the PWM data of the new COM, and switch to the next COM. After all the COM cycles are completed, there will be a complete display cycle and keyboard scanning cycle.

### 24.2.2 8-column RGB Internal Drive Application (8C\*3\*N)

The PWM pin mode for 8-column RGB internal drive applications is PA24.

Column driver is high-level efficient, driven by PA [23:0] a total of 24 PWM pins, each RGB tricolor LED

corresponds to a group of 3 PWM, a total of 8 columns. PA0/PA8/PA16 drives column 1 RGB, and so on, PA7/PA15/PA23 drives column 8 RGB.

The line driver is low-level and efficient, which is directly realized by multiple COM pins selected in PB [23:0]. No more than one COM pin at any time is low.

Support 24 columns \* multiple COM monochrome LED display matrix, 8 columns \* multiple COM RGB tricolor LED display matrix, the number of rows that is the number of COM depends on the number of PB pins available on the chip.

During initialization, the corresponding bit of the PWM pin used in the GPIOA\_OUTDR must be set to 0, which is effective by setting the output polarity to high level. The corresponding bit of the COM pin used in the GPIOB\_OUTDR must be set to 1 in order to set the output polarity to low level effective.

During the interruption, if you need current mode key detection, you can turn on the NKEY\_MODE bit of the LED\_KEY\_CTRL register, which will automatically turn off the output of the PWM pin, enable the pull-down, and enable the filling current detection circuit; set the COM\_PB\_INV bit, which is used to temporarily invert all COM outputs from display driving to key detection, which is convenient for key detection. Optionally, the COM\_LVE bit is set to avoid key misjudgment caused by reverse leakage of the LED when the COM output voltage is too high. If the input of any of the PA [15:0] pins is high, it means that the pin is pulled up by a certain COM (usually the current COM), that is, the key is detected. Because only one of the multiple COM is high, the matrix positioning of the key can be achieved, and the NKEY\_MODE and COM\_PB\_INV and COM\_LVE bits must be turned off after detection. During the interruption, the next row of display data is loaded. Writing 8 to LED\_DMA\_CNT means that you want DMA to load eight 32-bit data.

Other references are 16 columns of RGB external drive applications.

### 24.2.3 8-column RGB External Drive Application (8C\*3\*X)

There are three PWM pin modes for 8-column RGB external drive applications: PB24, PB16PA8 and PA24.

In PWM pin mode PB24, 24 PWM pins are driven by PB [23:0], PB0/PB8/PB16 drives column 1 RGB, and so on, PB7/PB15/PB23 drives column 8 RGB. Current mode button detection is supported.

In PWM pin mode PB16PA8, 24 PWM pins are driven by PB [15:0] and PA [23:16], PB0/PB8/PA16 drives column 1 RGB, and so on, PB7/PB15/PA23 drives column 8 RGB. Current mode button detection is supported.

In PWM pin mode PA24, 24 PWM pins are driven by PA [23:0], PA0/PA8/PA16 drives column 1 RGB, and so on, PA7/PA15/PA23 drives column 8 RGB. Current mode key detection is not supported.

Support 24 columns \* multiple COM monochrome LED display matrix, 8 columns \* multiple COM RGB tricolor LED display matrix, the number of rows that is the number of COM depends on the number of GPIO pins available on the chip. The main difference between the 8-column RGB external drive and the 16-column RGB external drive is that the PWM channel is only 8 columns, and the free PA or PB pins can be used for COM to drive external P-type MOSFET.

During initialization, the corresponding bits of the PWM pins used must be set to 1 in the GPIOx\_OUTDR to set the output polarity to low level. The corresponding bit of the COM pin used in the GPIOx\_OUTDR must be set to 1 in order to set the output polarity to low level effective.

During the interruption, the next row of display data is loaded. Writing 8 to LED\_DMA\_CNT means that you want DMA to load eight 32-bit data.

Other references are 16 columns of RGB external drive applications.

### 24.2.4 16-column Monochrome Internal Drive Application (16C\*1\*N)

The PWM pin mode for 16-column monochrome internal drive applications is PA16I.

Column driver is high-level efficient, driven by PA [15:0] a total of 16 PWM pins, each monochrome LED

corresponds to 1 PWM, a total of 16 columns.

The row driver is low-level and efficient, which is directly realized by multiple COM pins selected in PB [23:0]. No more than one COM pin at any time is low.

A monochrome LED display matrix with 16 columns \* multiple COM is supported. The number of rows, that is, the number of COM, depends on the number of PB pins available on the chip.

During initialization, the corresponding bit of the PWM pin used in the GPIOA\_OUTDR must be set to 0, which is effective by setting the output polarity to high level. The corresponding bit of the COM pin used in the GPIOB\_OUTDR must be set to 1 in order to set the output polarity to low level effective. In addition, the PA16I mode also needs to set PWM\_RED\_EN=1, PWM\_GREEN\_EN=1, PWM\_BLUE\_EN=0, and INTEN\_FULL=1 to match DMA data.

During the interruption, the next row of display data is loaded. Writing 8 to LED\_DMA\_CNT means that you want DMA to load eight 32-bit data. The lowest 8-bit data and the highest 8-bit data of every 32-bit data are not used, and any data can be filled, and the middle 2 8-bit data are 2 luminance PWM data in turn. All 32 bytes loaded by DMA come first with low bytes, and the corresponding PWM pins for each byte are as follows:

UNUSE / PA0 / PA8 / UNUSE.

UNUSE / PA1 / PA9 / UNUSE.

UNUSE / PA2;

UNUSE / PA7 / PA15 / UNUSE.

Others refer to 8 columns of RGB internal drive applications.

#### 24.2.5 5-column RGB Internal Drive Application (5C\*3\*N)

The PWM pin mode for 5-column RGB internal drive applications is PA15.

The column driver is high-level and efficient, and is driven by 15 PWM pins of PA [4:0] and PA [15:6]. Each RGB tricolor LED corresponds to a group of 3 PWM, a total of 5 columns. PA0/PA8/PA13 driver column 1 RGB, PA1/PA9/PA14 driver column 2 RGB, PA2/PA10/PA15 driver column 3 RGB, PA3/PA11/PA6 driver column 4 RGB, PA4/PA12/PA7 driver column 5 RGB.

The row driver is low-level and efficient, which is directly realized by multiple COM pins selected in PB [23:0]. No more than one COM pin at any time is low.

Support 15 columns \* multiple COM monochrome LED display matrix, 5 columns \* multiple COM RGB tricolor LED display matrix, the number of rows, that is, the number of COM depends on the number of PB pins available on the chip

During initialization, the corresponding bit of the PWM pin used in the GPIOA\_OUTDR must be set to 0, which is effective by setting the output polarity to high level. The corresponding bit of the COM pin used in the GPIOB\_OUTDR must be set to 1 in order to set the output polarity to low level effective.

During the interruption, the next row of display data is loaded. Writing 5 to LED\_DMA\_CNT means that you want DMA to load five 32-bit data.

Others refer to 8 columns of RGB internal drive applications.

#### 24.2.6 16-column Fully External Drive Application (X16C\*3\*X)

16-column RGB full external drive application reference 16-column RGB external drive application, PWM pin mode is PA24PB24.

The column driver is low-level and effective, which is realized by external N-type MOSFET or NPN transistor controlled by 48 PWM pins of PA [23:0] and PB [23:0] respectively. It is recommended to set constant current control or series current limiting resistor at the output of MOSFET or NPN.

The row driver is high-level and effective, which is realized by a plurality of COM pins to control the external P-

type MOSFET, and no more than one COM pin is low at any time, and the high level is output through the external P-type MOSFET inverter.

During initialization, the corresponding bit of the PWM pin used in the GPIOx\_OUTDR must be set to 0, which is effective by setting the output polarity to high level. The corresponding bit of the COM pin used in the GPIOx\_OUTDR must be set to 1 in order to set the output polarity to low level effective.

For key detection, you can use regular voltage mode and use additional GPIO pins to enable pull-up as column sampling input. If any GPIO pull-up pin input is detected to be low, the pin is pulled down by a COM (usually the current COM), that is, a key is detected.

If current-mode key detection is required to save GPIO pins, then the PA [15:0] pin should choose an N-type MOSFET with a higher turn-on voltage ( $V_{GS} > 1.4V$ ), otherwise the key scanning process will cause the LED to shine. During the interruption, turning on the NKEY\_MODE bit of the LED\_KEY\_CTRL register will automatically turn off the output of the PWM pin, enable the pull-down, and enable the filling current detection circuit; set the COM\_PB\_INV bit, which is used to temporarily invert all COM outputs from display driving to key detection, which is convenient for key detection. If any input of the PA [15:0] pin is detected as high, the pin is pulled up by a COM (Usually the current COM), that is, the key is detected. The NKEY\_MODE and COM\_PB\_INV bits need to be turned off after detection.

## 24.3 Register Description

Table 24-1 LEDPWM-related registers

| Name              | Access address | Description                                    | Reset value |
|-------------------|----------------|------------------------------------------------|-------------|

Offset address: 0x16

| Bit   | Name           | Access | Description                                                                                                                                                            | Reset value |
|-------|----------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [7:0] | GREEN_ADJ[7:0] | RW     | The LED green adjustment value, -128 to 127, the highest bit is the symbol, which is automatically added when the green data is loaded and then sent to the green PWM. | 0           |

### 24.3.30 LED Blue Adjustment Register (LED\_BLUE\_ADJ)

Offset address: 0x17

| Bit   | Name          | Access | Description                                                                                                                                                         | Reset value |
|-------|---------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [7:0] | BLUE_ADJ[7:0] | RW     | The LED blue adjustment value, -128 to 127, the highest bit is the symbol, which is automatically added when the blue data is loaded and then sent to the blue PWM. | 0           |

### 24.3.31 LED DMA Buffer Current Address Register (LED\_DMA)

Offset address: 0x18

| Bit    | Name      | Access | Description                                                                                                                                | Reset value |
|--------|-----------|--------|--------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| [15:0] | DMA[15:0] | RW     | LED DMA current address, automatically incremented when DMA is loaded. The lower 16 bits are valid and the address must be 4-byte aligned. | 0           |

## 24.4 Application Circuit Reference

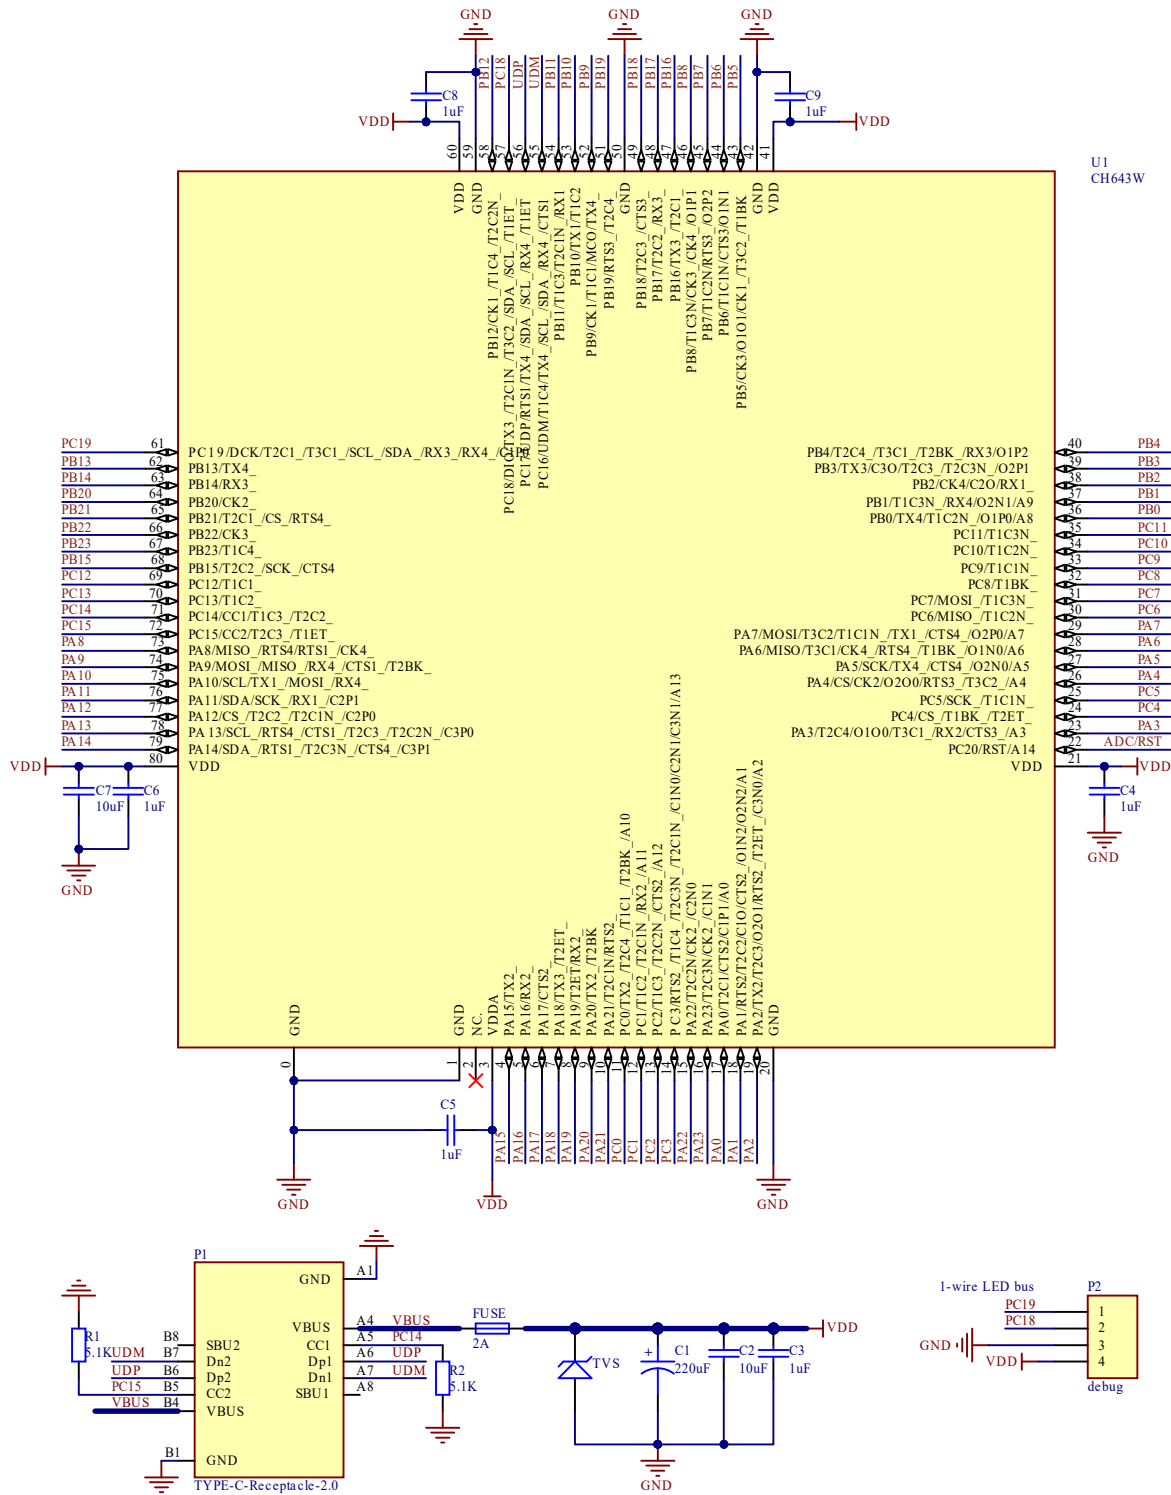

### 24.4.1 Minimum System

CH643 supports 5V power supply, supports USB communication, supports USB PD to obtain large current, and has a compact periphery. It is recommended that 5V power supply VDD plus TVS and other over-voltage protection and over-current protection, and there are more ground capacitors, high-frequency capacitors should be as close to the chip as possible.

PC19 can be used to drive the LED lamp string of single-wire protocol, and PC20 can be used for battery voltage sampling or external reset input.

The polar connection of the LED or diode of the external drive mode is opposite to that of the internal drive mode; the VDD current of the internal drive mode is equal to that of the GND current, usually below 300mA; the VDD current of the external drive mode is very small, and the GND current is very large, up to 600mA or even 1A. The complete external drive mode does not need to consider the temperature and heat dissipation of the CH643 chip itself, but needs to consider the overall current and heat dissipation, which can reach 3A.

The wire width, number of holes, current capacity, voltage drop and heat dissipation should be considered in the design of PCB.

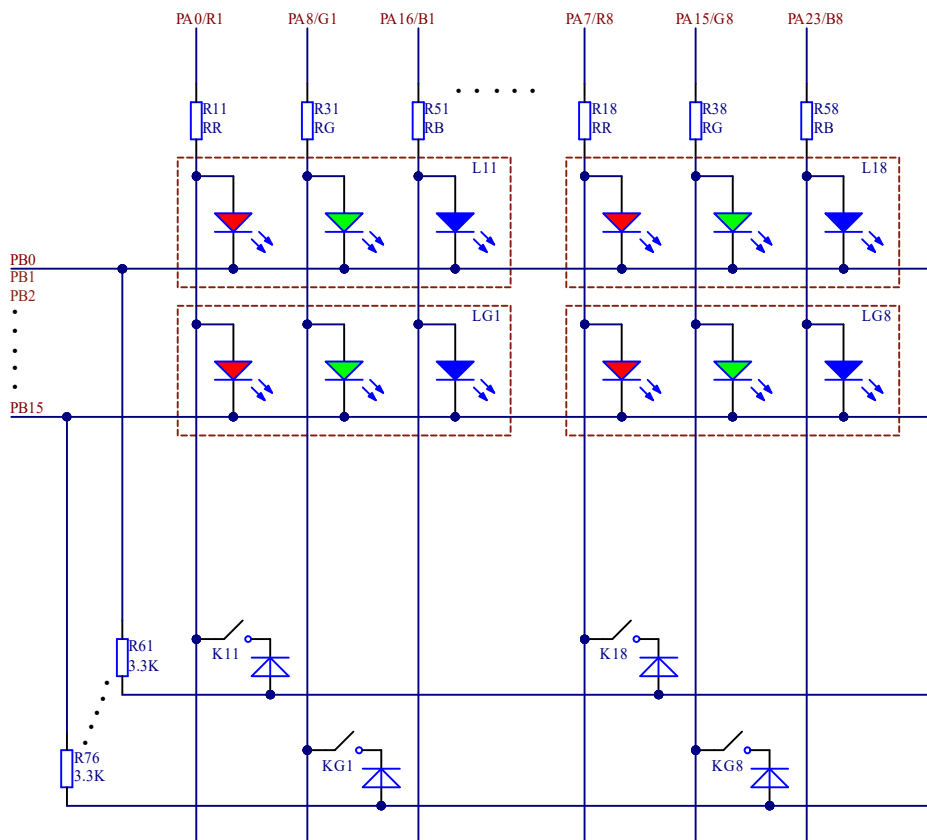

### 24.4.2 16 Rows\*8 Columns RGB Internal Driver +16 Rows\*8 Keyboards

Referring to the following figure, the upper part is the LED driver matrix L11-LG8, and the lower part is the keyboard matrix K11-KG8.

PA0-PA23 drives 8 columns of RGB. Resistors R11-R18, R31-R38 and R51-R58 limit the LED of red, green and blue columns respectively. Not only can we choose three different resistance values of RR, RG and RB to adjust the color difference of RGB, but also can be used to disperse the voltage drop to reduce CH643 temperature. If we do not use current-limiting resistors and rely on the constant current inside the chip, the CH643 temperature will be higher. The total current of the full built-in COM drive mode should take into account not only the continuous current capability of the VDD pin and the pulse current capability of the COM pin, but also the chip temperature and heat dissipation.

PB0-PB15 drives 16 rows directly. In the figure, the three LED of RGB can share a common-shaded RGB tricolor LED.

After series resistors respectively, PB0-PB15 and PA0-PA15 form 16\*16 keyboard matrix. In order to realize full-key impulse-free (No conflict and no misjudgment when multiple keys are pressed at the same time), each key needs a series of anti-collision diodes. If no more than 128 keystrokes are needed, one keystroke can be interlaced and canceled at intervals in the matrix to get a 16-keypad matrix, thus reducing the collision probability. CH643 can support current-mode key detection to multiplex LED drive pins and save I/O resources. The resistor R61-R76 is used to limit the key current. If the resistance value is too large, the key detection response is slow or even cannot be detected. If the resistance value is too small, multiple keys pressed at the same time may cause LED to shine slightly.

### 24.4.3 16 Rows\*16 Columns RGB External Driver +16 Rows\*16 Keyboards

Referring to the following figure, the upper part is the keyboard matrix K11-KGG, and the lower part is the LED driver matrix L11-LGG.

PA0-PA23 and PB0-PB23 drive 16 columns of RGB. Resistors R11-R26, R31-R46 and R51-R66 limit the LED of red, green and blue columns respectively. Not only can we choose three different resistance values of RR, RG and RB to adjust the color difference of RGB, but also can be used to disperse the voltage drop to reduce CH643 temperature. If we do not use current-limiting resistors and rely on the constant current inside the chip, the CH643 temperature will be higher. The total current driven by external PMOS should consider not only the continuous current capability of GND pin and PWM pin, but also the chip temperature and heat dissipation.

PC0-PC15 controls 16 external P-type MOSFET devices to drive 16 rows. In the figure, the three LED of RGB can share a common positive structure of RGB tricolor LED. The internal resistance and current capacity of MOSFET devices are selected according to the brightness requirements and the total current. It is recommended that the R<sub>dson</sub> is less than 400mohm, and the voltage drop is not more than 0.4V when passing through 1A current, which can be appropriately relaxed for lower brightness.

After series resistors, PC0-PC15 and PB0-PB15 form a 16\*16 keyboard matrix. In order to achieve full keys without impulse, each key needs to be connected in series with anti-collision diodes. CH643 can support current-mode key detection to multiplex LED drive pins and save I/O resources. The resistor R61-R76 is used to limit the key current. If the resistance value is too large, the key detection response is slow or even cannot be detected. If the resistance value is too small, multiple keys pressed at the same time may cause LED to shine slightly.
