

CH641 Reference Manual

V1.3 https://wch-ic.com

Overview

The CH641 series is a dedicated MCU for PD wireless charging designed based on the QingKe RISC-V2A core. It supports 2-level interrupt nesting, has built-in PDPHY, BC interface, differential input current sampling and AC small signal amplification decoder, and supports USB PD and Type-C fast charging function, BC1.2 and other charging protocols, provides ADC, timer, serial port, I2C and other peripheral resources, and provides over-voltage protection and over-temperature protection.

This manual provides detailed usage information of the CH641 series microcontrollers for users' application development. It is applicable to products with different memory capacities, functional resources, and packages in the series. If there are any differences, special explanations will be made in the corresponding function chapters.

For the device characteristics of this product, please refer to the datasheet *CH641DS0*. For information about the core, refer to *QingKeV2_Processor_Manual*.

| Features Core versions | Instruction set | Hardware stack levels | Interrupt nesting levels | Fast interrupt channels | Flow line | Vector table model | Extended instruction | Debug interface |
|------------------------------|--------------------|-----------------------------|--------------------------------|-------------------------------|--------------|-----------------------|----------------------|--------------------|
| QingKe V2A | RV32EC | 2 | 2 | 2 | 2 | Address or command | Supported | 1-wire |

RISC-V core version comparison overview

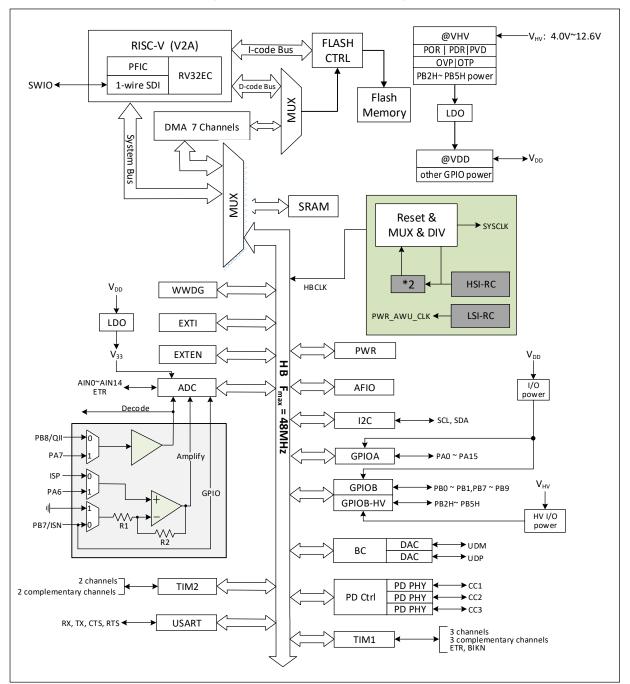

Abbreviated description of the bit attribute in the register:

| Register bit attributes | Property description |
|----------------------------|---|
| RF | Read-only attribute, read a fixed value. |
| RO | Read-only attribute, changed by hardware. |
| RZ | Read-only attribute, auto bit clear 0 after read operation. |
| WO | Write only attribute (not readable, read value uncertain) |
| WA | Write-only attribute, writable in Safe mode. |
| WZ | Write only attribute, auto bit clear 0 after write operation. |
| RW | Readable and writable. |
| RWA | Readable, writable in Safe mode. |
| RW1 | Readable, write 1 valid, write 0 invalid. |
| RW0 | Readable, write 0 valid, write 1 invalid. |
| RW1T | Readable, write 0 invalid, write 1 flipped. |

Chapter 1 Memory and Bus Architecture

1.1 Bus Architecture

CH641 is based on the RISC-V instruction set, and its architecture realizes the interaction of the core, arbitration unit, DMA module, SRAM memory and other parts through multiple buses. The design integrates a general-purpose DMA controller to reduce the load on the CPU and improve the access efficiency, while at the same time, it also has a data protection mechanism, automatic clock switching protection and other measures to increase the stability of the system. Its system block diagram is shown in Figure 1-1.

The system is equipped with: General-purpose DMA controller to reduce the CPU load and improve efficiency;

clock tree hierarchy management to reduce the total power consumption of peripherals, as well as data protection mechanisms, clock security system protection mechanisms and other measures to increase system stability.

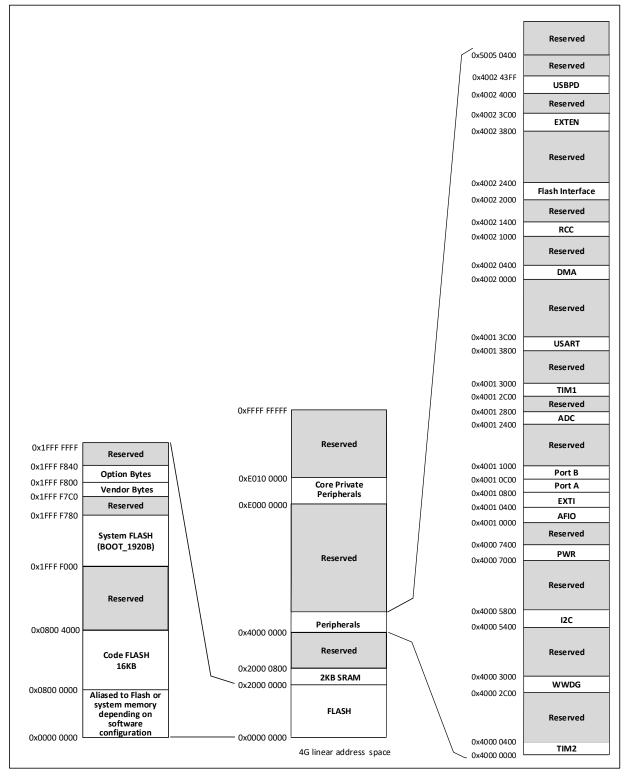

- The instruction bus (I-Code) connects the core to the FLASH instruction interface and prefetching is done on this bus.
- The data bus (D-Code) connects the core to the FLASH data interface for constant loading and debugging.
- The system bus connects the core to the bus matrix and is used to coordinate accesses to the core, DMA, SRAM and peripherals.
- The DMA bus is responsible for the DMA of the HB master interface connected to the bus matrix, which is accessed by FLASH data, SRAM and peripherals.
- The bus matrix is responsible for the access coordination between the system bus, data bus, DMA bus, SRAM and HB bridge.

1.2 Memory Map

The CH641 family contains program memory, data memory, core registers, peripheral registers, and more, all addressed in a 4GB linear space.

System storage stores data in small-end format, i.e., low bytes are stored at the low address and high bytes are stored at the high address.

1.2.1 Memory Allocation

Built-in 2KB SRAM, starting address 0x2000000, supports byte, half-word (2 bytes), and full-word (4 bytes) access.

Built-in up to 16KB program Flash memory (CodeFlash) for storing user applications.

Built-in 1920-byte SystemFlash, or BOOT area, is used for system bootloader storage (factory-cured bootloader), and can also be used for user application program and constant data storage after setting the user configuration word START_MODE bit to 0 to turn off the BOOT (ld segmented link file required).

Built-in 64B space for vendor configuration word storage, factory-cured and unmodifiable by users.

Built-in 64B space for user option byte storage.

Chapter 2 Power Control (PWR)

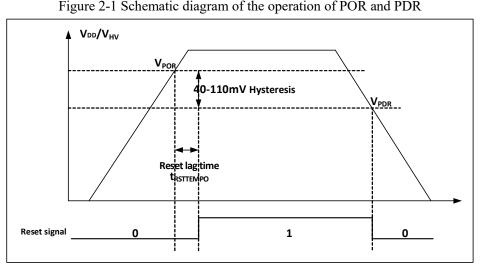

2.1 Overview

The system operating voltage V_{HV} range is $4.0 \sim 12.6V$.

2.2 Power Management

2.2.1 Power-on Reset and Power-down Reset

The system integrated a power-on reset POR and a power-down reset PDR circuit. When the chip supply voltage V_{HV} or V_{DD} falls below the corresponding threshold voltage, the system is reset by the relevant circuit, and no additional external reset circuit is required. Please refer to the corresponding datasheet for the parameters of the power-on threshold voltage V_{POR} and the power-down threshold voltage V_{PDR}.

2.2.2 Programmable Voltage Detector

The programmable voltage detector, PVD, is mainly used to monitor the change of the main power supply of the system and compare it with the threshold voltage set by PLS[2:0] of the power control register PWR CTLR, and with the external interrupt register (EXTI) setting, it can generate relevant interrupts to notify the system in time for pre-power down operations such as data saving.

The specific configuration is as follows.

1) Set the PLS[1:0] field of the PWR CTLR register and select the voltage threshold to be monitored.

2) Optional interrupt handling, the PVD function is internally connected to the rising/falling edge trigger setting of line 16 of the EXTI module, turning on this interrupt (configuring EXTI) will generate a PVD interrupt when V_{HV} drops below the PVD threshold or rises above the PVD threshold.

3) Set the PVDE bit of PWR CTLR register to enable PVD function.

4) Read PVD0 bit of PWR CSR status register can obtain the relationship between the current system main power supply and PLS[2:0] setting threshold, and perform corresponding soft processing. When the VDD voltage is higher than the threshold set by PLS[2:0], the PVD0 position is 0; When the VDD voltage is lower than the PLS[2:0] set threshold, the PVD0 bit is set.

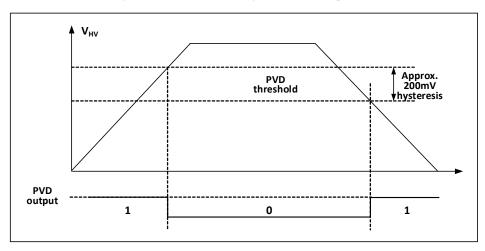

Figure 2-2 Schematic diagram of PVD operation

2.2.3 Overvoltage Reset

The system continuously monitors the V_{HV} supply voltage internally and generates a reset when the V_{HV} voltage is higher than V_{OVP} .

2.3 Low-power Modes

After a system reset, the microcontroller is in a normal operating state (Run mode), where system power can be saved by reducing the system main frequency or turning off the unused peripheral clock or reducing the operating peripheral clock. If the system does not need to work, you can set the system to enter low-power mode and let the system jump out of this state by specific events.

Microcontrollers currently offer 2 low-power modes, divided in terms of operating differences between processors, peripherals, voltage regulators, etc.

- Sleep mode: The core stops running and all peripherals (including core private peripherals) are still running.
- Standby mode: Stops all clocks and the system continues to run after waking up.

| Mode | Entry | Wake-up source | Effect on clock | Voltage regulator |
|--------|---|--|---|-------------------|
| | WFI | Any interrupt | Core clock OFF, | |
| Sleep | WFE | Wake-up event | no effect on other clocks | Normal |
| Standy | Set SLEEPDEEP to 1 Set PDDS to1 WFI or WFE | Any external interrupt/event (EXTI signal), external reset signal on RST, USB PD wakeup signal, PVD output, AWU auto- wakeup, the EXTI signal includes one of the 25 external I/O ports. | Disable HIS, PLL and peripheral clock | Off |

Note: The SLEEPDEEP bit belongs to the core private peripheral control bit, CH641 refers to the PFIC_SCTLR register.

2.3.1 Low-power Configuration Options

• WFI and WFE

WFI: The microcontroller is woken up by an interrupt source with interrupt controller response, and the interrupt service function will be executed first after the system wakes up (except for microcontroller reset).

WFE: The wakeup event triggers the microcontroller to exit low-power mode. Wake-up events include:

- 1) Configure an external or internal EXTI line to event mode, when no interrupt controller needs to be configured.
- 2) Or configure an interrupt source, equivalent to a WFI wakeup, where the system prioritizes the execution of the interrupt service function.
- 3) Or configure the SEVONPEND bit to turn on peripheral interrupt enable, but not interrupt enable in the interrupt controller, and the interrupt pending bit needs to be cleared after the system wakes up.

• SLEEPONEXIT

Enable: After executing the WFI or WFE instruction, the microcontroller ensures that all pending interrupt services are exited and then enters low-power mode.

Not enabled: The microcontroller enters low-power mode immediately after executing the WFI or WFE command.

• SEVONPEND

Enable: All interrupts or wake-up events can wake up the low-power consumption entered by executing WFE.

Not enabled: Only interrupts or wake-up events enabled in the interrupt controller can wake up the low-power consumption entered by executing WFE.

2.3.2 Sleep Mode (SLEEP)

In this mode, all I/O pins keep their state in Run mode and all peripheral clocks are normal, so try to turn off useless peripheral clocks before entering Sleep mode to reduce low-power consumption. This mode takes the shortest time to wake up.

Enter: Configure core register control bit SLEEPDEEP=0, power control register PDDS=0, execute WFI or WFE, optionally SEVONPEND and SLEEPONEXIT.

Exit: Arbitrary interrupt or wakeup event.

2.3.3 Standby Mode (STANDBY)

Standby mode is based on the core's deep sleep mode (SLEEPDEEP), combined with the clock control mechanism of the peripherals, and allows the voltage regulator to operate in a lower power consumption state. In this mode, the high-frequency clock (HSI/PLL) domain is turned off, the SRAM and register contents are maintained, and the IO pin status is maintained. The system can continue to run after waking up in this mode, with HSI as the default system clock.

If flash programming is in progress, the system does not enter standby mode until the memory access is complete. Modules that can work in Standby mode: low-frequency clock (LSI).

Enter: Configure the core register control bit SLEEPDEEP=1, PDDS=1 in the power control register, and execute WFI or WFE, optionally SEVONPEND and SLEEPONEXIT.

Exit: Any external interrupt/event (EXTI signal), external reset signal on RST, USBPD wake-up signal, PVD output, AWU automatic wake-up, where the EXTI signal includes one of the 25 external I/O ports

2.3.4 Auto-wakeup (AWU)

Automatic wake-up without external interrupt can be realized. Periodic wake-up from low-power mode is possible by programming the time base.

The selectable internal low-frequency clock oscillator LSI divides by 60000 as the automatic wake-up counting time base.

2.4 Register Description

Chapter 3 Reset and Clock Control (RCC)

The controller provides different forms of resets and configurable clock tree structures based on the division of power areas and peripheral power management considerations in the application. This section describes the scope of each clock in the system.

3.1 Main Features

- Multiple reset forms
- Multiple clock sources, bus clock management
- Independent management of each peripheral clock: Reset, On, Off
- Supports internal clock output

3.2 Reset

The controller provides 3 forms of reset: Power reset, system reset, overtemperature or overvoltage reset.

3.2.1 Power Reset

When a power reset occurs, it will reset all registers.

A power Reset is generated when the following event occurs:

• Power-up/power-down reset (POR/PDR)

3.2.2 System Reset

When a system reset occurs, it will reset the reset flag in addition to the control/status register RCC_RSTSCKR and all the registers. The source of the reset event is identified by looking at the reset status flag bit in the RCC_RSTSCKR register.

A system reset is generated when one of the following events occurs:

- Low signal on NRST pin (external reset)
- Window watchdog count termination (WWDG reset)
- Software reset (SW reset)
- USBPD reset
- Low-power management reset
- OVP overvoltage reset

Window watchdog reset: triggered by the window watchdog external timer count cycle overflow, see the corresponding chapter for detailed description.

Software reset: The CH641 resets the system via RSTSYS position 1 of the Interrupt Configuration Register PFIC_CFGR in the Programmable Interrupt Controller PFIC or SYSRST position 1 of the Configuration Register PFIC SCTLR in the System Cabinet, refer to the corresponding section.

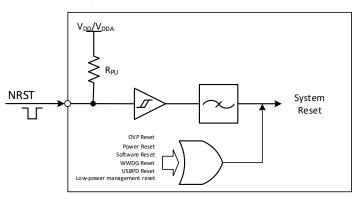

USBPD reset: CH641 supports the reset generated by USB PD signal frame Hard Reset when PD_RST_EN is 1, and also supports the reset generated by signal frame Cable Reset if IE_RX_RESET is also 1. USB PD does not have a reset flag, but the reset effect is the same as the software reset.

Low Power Management reset: Standby mode reset is enabled by setting the STANDBY_RST bit in the user select byte. After executing the process of entering standby mode at this time, a system reset will be executed instead of

entering Standby mode.

OVP overvoltage reset: triggered when the $V_{\rm HV}$ voltage is higher than $V_{\rm OVP}.$

Figure 3-1 System reset structure

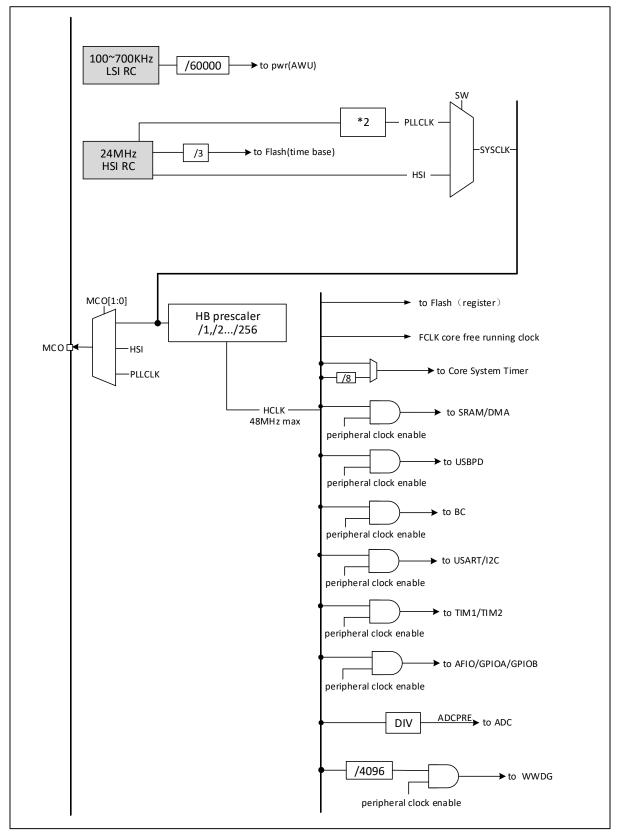

3.2.3 Overtemperature Reset

CH641 has a built-in overtemperature protection (OTP)module, which will forcefully reset the MCU when the chip temperature is too high.

3.3 Clock

3.3.1 System Clock Structure

3.3.2 High-speed Internal Clock (HSI)

HSI is a high-speed clock signal generated by the 24MHz RC oscillator inside the system. The HSIRC oscillator provides the system clock without the need for any external components. Its startup time is very short. HSI is enabled and disabled by setting the HSION bit in the RCC_CTLR register, and the HSIRDY bit indicates whether the HSIRC oscillator is stable. By default, HSION and HSIRDY are set to 1 by the system (it is recommended not to turn them off). If the HSIRDYIE bit of the RCC_INTR register is set, the corresponding interrupt will be generated.

- Factory calibration: The difference of manufacturing process will cause different RC oscillation frequency for each chip, so HSI calibration is performed for each chip before it is shipped. After system reset, the factory calibration value is loaded into HSICAL[7:0] of the RCC_CTLR register.
- User tuning: Based on different voltages or ambient temperatures, the application can adjust the HSI frequency by using the HSITRIM[4:0] bits in the RCC_CTLR register.

3.3.3 Low-speed Internal Clock (LSI)

LSI is a low-speed clock signal generated by the RC oscillator inside the system. It can remain running in standby mode to provide a clock reference for waking up the unit. Further information can be found in the Electrical Characteristics section of the datasheet.

3.3.4 PLL Clock

The PLL clock is turned on and off by setting the PLLON bit in the RCC_CTLR register. The PLLRDY bit indicates whether the PLL clock is stable or not, and the hardware sends the clock into the system only after PLL position 1. If the PLLRDYIE bit in the RCC_INTR register is set, a corresponding interrupt is generated. PLL clock source: HSI clock input.

3.3.5 Bus/Peripheral Clock

3.3.5.1 System Clock (SYSCLK)

Configure the system clock source by configuring the SW[1:0] bits of the RCC_CFGR0 register. SWS[1:0] indicates the current system clock source.

- HSI as system clock
- PLL clock as system clock

After the controller is reset, the default HSI clock is selected as the system clock source. Switching between clock sources must not occur until the target clock source is ready.

3.3.5.2 HB Bus Peripheral Clock (HCLK)

The HB bus clocks can be configured by configuring the HPRE[3:0] bits of the RCC_CFGR0 register. The bus clock determines the peripheral interface access clock reference that is mounted below them. Applications can adjust different values to reduce the power consumption when some of the peripherals are operating.

The various bits in the RCC_APB1PRSTR and RCC_APB2PRSTR registers can reset the different peripheral modules to their initial state.

Each bit in the RCC_AHBPCENR, RCC_APB1PCENR, and RCC_APB2PCENR registers can be used to individually turn on or off the communication clock interface for different peripheral modules. When using a peripheral, you first need to turn on its clock enable bit in order to access its registers.

3.3.5.3 Microcontroller Clock Output (MCO)

The microcontroller allows outputting clock signals to the MCO pins. The following 4 clock signals can be selected as MCO clock outputs by configuring the alternate push-pull output mode in the corresponding GPIO port registers by configuring the MCO[2:0] bits of the RCC_CFGR0 register.

- System clock (SYSCLK) output
- HSI clock output
- PLL clock output

Chapter 4 Window Watchdog (WWDG)

Window Watchdog is generally used to monitor system operation for software faults such as external disturbances, unforeseen logic errors, and other conditions. It requires a counter refresh (dog feeding) within a specific window time (with upper and lower limits), otherwise earlier or later than this window time the watchdog circuit will generate a system Reset.

4.1 Main Features

- Programmable 7-bit down-counter
- Biconditional reset: the down-counter value is less than 0x40, or the counter value is reloaded outside the window time
- Wake Up Early Notification (EWI) function for timely dog feeding action to prevent system Reset

4.2 Function Description

4.2.1 Principle and Application

The window watchdog operation is based on a 7-bit down-counter, which is mounted under the HB bus and counts the dividing frequency of the time base WWDG_CLK source (HCLK/4096) clock with the dividing factor set in the WDGTB[1:0] field in the configuration register WWDG_CFGR. The down-counter is in the free-running state, and the counter keeps counting down in a loop regardless of whether the watchdog function is on or not. As shown in Figure 4-1, the block diagram of the internal structure of the window watchdog.

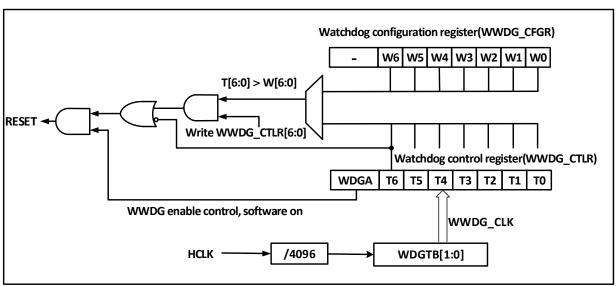

Figure 4-1 Block diagram of Window Watchdog structure

• Enable Window Watchdog

After a system Reset, the watchdog is off. Setting the WDGA bit of the WWDG_CTLR register enables the watchdog, and then it cannot be turned off again unless a reset occurs.

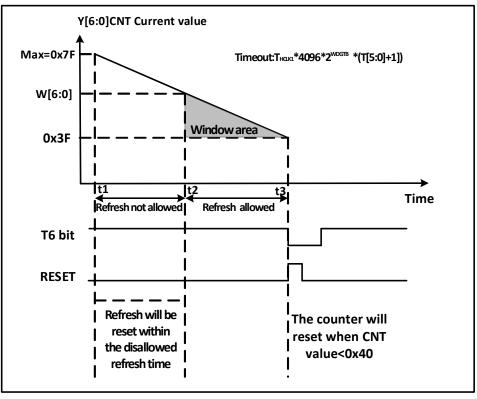

Note: The watchdog function can be stopped indirectly by setting the RCC_APB1PCENR register to turn off the clock source of WWDG and suspend the WWDG_CLK count, or by setting the RCC_APB1PRSTR register to reset the WWDG module, which is equivalent to the role of reset.

• Watchdog Configuration

The watchdog is internally a 7-bit counter that runs in a continuous decreasing cycle and supports read and write access. To use the watchdog reset function, the following actions need to be performed.

- 1) Counting time base: via the WDGTB[1:0] bit field of the WWDG_CFGR register, note that the WWDG module clock of the RCC unit should be turned on.
- 2) Window counter: Set the W[6:0] bit field of WWDG_CFGR register, this counter is used by hardware as a comparison with the current counter, the value is configured by user software and will not change. It is used as the upper limit value of the window time.
- 3) Watchdog enable: WDG_CTLR register WDGA bit software set to 1, to turn on the watchdog function, you can system reset.
- 4) Feed the dog: i.e., refresh the current counter value and configure the T[6:0] bit field of the WWDG_CTLR register. This action needs to be executed within the periodic window time after the watchdog function is turned on, otherwise a watchdog reset action will occur.
- Dog feeding window time

As shown in Figure 4-2, the gray area is the monitoring window area of the window watchdog, whose upper time t2 corresponds to the point in time when the current counter value reaches the window value W[6:0]; its lower time t3 corresponds to the point in time when the current counter value reaches 0x3F. This area time t2<t<t3 can be fed with a dog operation (write T[6:0]) to refresh the current counter value.

- Watchdog reset
- When the value of T[6:0] counter changes from 0x40 to 0x3F due to no timely dog feeding operation, a "window watchdog reset" will occur and a system reset will be generated. That is, the T6-bit is detected as 0 by the hardware and a system reset will occur.

Note: The application can write T6-bit to 0 by software to achieve system Reset, which is equivalent to software

reset function.

2) When the counter refresh action is executed within the disallowed dog feeding time, i.e., the write T[6:0] bit field is operated within $t_1 \le t \le t_2$ time, a "window watchdog reset" will occur and a system Reset will be generated.

• Wake up in advance

To prevent the system Reset caused by not refreshing the counter in time, the watchdog module provides an early wakeup interrupt (EWI) notification. When the counter self-decreases to 0x40, an early wake-up signal is generated and the EWIF flag is set to 1. If the EWI bit is set, a window watchdog interrupt will be triggered at the same time. At this time, there is 1 counter clock cycle (self-decrement to 0x3F) before the hardware reset, and the application can perform the dog feeding operation instantly within this time.

4.2.2 Debug Mode

When the system enters Debug mode, the counter of WWDG can be configured by the debug module register to continue or stop.

4.3 Register Description

| [15:1] | Reserved | WO | Reserved | 0 |
| 0 | EWIF | KW0 | Wake up the interrupt flag bit early. When the counter reaches 0x40, this bit is set in hardware and must be cleared to 0 by software; the user setting is invalid. Even if the EWI is not set, this bit will still be set as usual when the event occurs. | 0 |

Chapter 5 Interrupt and Events (PFIC)

The CH641 series has a built-in Programmable Fast Interrupt Controller (PFIC) that supports up to 255 interrupt vectors. The current system manages 25 peripheral interrupt channels and 4 core interrupt channels, the others are reserved.

5.1 Main Features

5.1.1 PFIC

- 25 peripheral interrupts, each interrupt request has independent trigger and mask control bits, with dedicated status bits
- Programmable multi-level interrupt nesting, maximum nesting depth 2 levels, hardware stack depth 2 levels
- Fast interrupt entry and exit mechanism, hardware automatic stacking and recovery
- Vector Table Free (VTF) interrupt response mechanism, 2-way programmable direct access to interrupt vector addresses

5.2 System Timer

• CH641 Series

The core comes with a 32-bit add counter (SysTick) that supports HCLK or HCLK/8 as a time base with high priority and can be used as a time reference after calibration.

5.4 External Interrupt and Event Controller (EXTI)

5.4.1 Overview

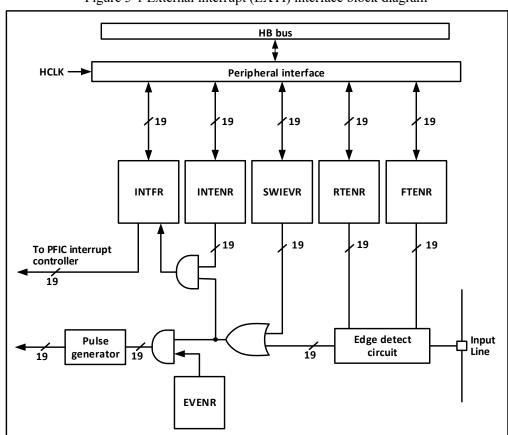

Figure 5-1 External interrupt (EXTI) interface block diagram

As can be seen from Figure 5-1, the trigger source of the external interrupt can be either a software interrupt (SWIEVR) or an actual external interrupt channel. The signal of the external interrupt channel will be screened by the edge detect circuit first. Whenever one of the software interrupt or external interrupt signals is generated, it will be output to two AND gate circuits, event enable and interrupt enable, through the OR gate circuit in the figure, as

long as an interrupt is enabled or an event is enabled, an interrupt or an event will be generated. six registers of EXTI are accessed by the processor through the HB interface.

5.4.2 Wake-up Event

The system can wake up the Sleep mode caused by the WFE command through a wake-up event. The wake-up event is generated by either of the following two configurations.

- Enable an interrupt in a peripheral register, but not enabling this interrupt in the PFIC of the core, and enabling the SEVONPEND bit in the core at the same time. Embodied in EXTI, it is to enable an EXTI interrupt, but not to enable the EXTI interrupt in PFIC, and to enable the SEVONPEND bit at the same time. When the CPU wakes up from WFE, it needs to clear the EXTI interrupt flag bit and the PFIC pending bit.
- Enable an EXTI channel as an event channel eliminates the need for the CPU to clear the interrupt flag bit and the PFIC pending bit after waking up from the WFE.

5.4.3 Description

Using an external interrupt requires configuring the corresponding external interrupt channel, i.e. selecting the corresponding trigger edge and enabling the corresponding interrupt. When the set trigger edge appears on the external interrupt channel, an interrupt request will be generated and the corresponding interrupt flag bit will be set. The flag bit can be cleared by writing 1 to the flag bit.

Steps for using external hardware interrupts.

- 1) Configuration of GPIO operations.
- 2) Configure the interrupt enable bit (EXTI_INTENR) for the corresponding external interrupt channel.
- 3) Configuring the trigger edge (EXTI_RTENR or EXTI_FTENR) to select rising edge trigger, falling edge trigger or double edge trigger.
- 4) Configure EXTI interrupts in the core's PFIC to ensure they can respond correctly.

Steps for using external hardware events.

- 1) Configuration of GPIO operations.
- 2) Configure the event enable bit (EXTI_EVENR) for the corresponding external interrupt channel.
- 3) Configure the trigger edge (EXTI_RTENR or EXTI_FTENR) to select rising edge trigger, falling edge trigger, or double edge trigger.

Using the software interrupt/event steps.

- 1) Enabling external interrupts (EXTI_INTENR) or external events (EXTI_EVENR).
- 2) If using interrupt service functions, the EXTI interrupt needs to be set in the core's PFIC.
- 3) Set the software interrupt trigger (EXTI_SWIEVR), that is, an interrupt will be generated.

5.4.4 External Event Mapping

| Mapping event description |
|--|
| $Px0 \sim Px15$ (x=A/B), any of the I/O ports can be enabled for |
| external interrupt/event functions, configured by the |
| AFIO_EXTICRx register. |
| PVD event: voltage monitoring threshold exceeded |
| AWU auto-wakeup event |
| USB PD wakeup event |

5.5.3 Dedicated CSR Registers

A number of Control and Status Registers (CSRs) are defined in the RISC-V architecture to configure or identify or record operational status. In addition to the standard registers defined in the RISC-V Privileged Architecture document, the CH641 chip also has a number of vendor-defined registers that need to be accessed using the csr instruction.

Note: These registers are labeled "MRW, MRO, MRW1" and require the system to be in machine mode to access them.

5.5.3.1 Interrupt System Control Register (INTSYSCR)

| CS | R addro | ess: 0x8 | 804 | | | | | | | | | | | | |
|----|---------|----------|-----|----|----|------|-------|-------|----|----|----|----|----|-----------------|-----------------|

Chapter 6 GPIO and Alternate Function (GPIO/AFIO)

The GPIO port can be configured into a variety of input or output modes, with a built-in pull-up or pull-down resistor that can be turned off, and can be configured as a push-pull output. The GPIO port can also be reused for other functions.

PB2H, PB3H, PB4H, and PB5H are V_{HV} -powered high-voltage I/O pins, and the rest are V_{DD} -powered low-voltage I/O pins.

PA2, PA3, PA4, PA5, and PA9 all have strong current driving capabilities, which is about twice that of other ordinary I/O pins.

When PB8 is used as a GPIO, it only supports input or open-drain output, and does not support push-pull output.

PB6 has no GPPB3H and PB4H have built-in pull-up resistors that cannot be turned off; PB2H and PB5H do not have built-in pull-up resistors; ISP and PB8/QII do not have built-in pull-up resistors; PA0 and PA1 have built-in pull-up resistors that are turned off by default and can be adjusted, and are controlled by 2 EXTEN_CTLR1 PUE and DAC are adjusted and controlled, and can provide pull-up current; 3 CC pins are provided, of which PB0/CC1R and PB9/CC3R pins have built-in controllable Rd pull-down resistors defined by the type-C specification, and PB1/CC2 pins The pin does not provide Rd by default, but can support customization and is controlled by CC_PU in R8_PORT_CC of the corresponding pin; other GPIO pins have built-in pull-up resistors that are turned off by default and can be adjusted on JO function and is used only for ISP input.

PA4 and PA5 have built-in pull-down resistors that are enabled by default and can be disabled; PA0 and PA1 have built-in pull-down resistors that are enabled by default and can be adjusted or disabled, which are adjusted and controlled by two sets of PDE and DAC in EXTEN_CTLR1 and can provide pull-down current; PB0/CC1R and PB9/CC3R pins have built-in controllable Rd pull-down resistors defined by the default type-C specification, which are enabled by default and need to be disabled when used as GPIO push-pull outputs. PB1/CC2 pins do not provide Rd by default, but can be customized and controlled by CC_PD in R8_PORT_CC of the corresponding pins; other GPIO pins do not have built-in pull-down resistors.

6.1 Main Features

Each pin of the port can be configured to one of the following multiple modes.

- Floating input
- Pull-up input
- Pull-down input (partial IO)

- Analog input
- Push-pull output
- Inputs and outputs of alternate function

Many pins have alternate capabilities, and many other peripherals map their output and input channels to these pins. The specific usage of these alternate pins needs to be referred to the individual peripherals, and the content of whether these pins are alternate and remapped is explained in this chapter.

6.2 Function Description

6.2.1 Overview

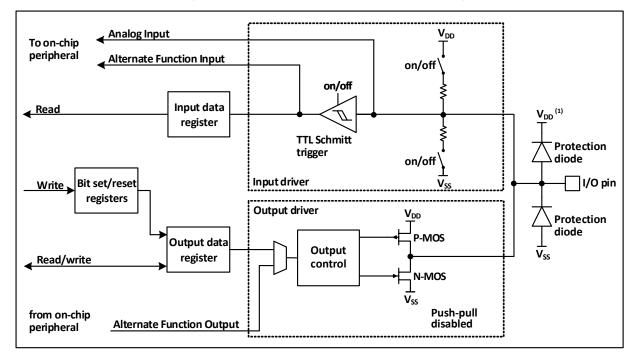

Figure 6-1 GPIO module basic structure block diagram

Note: (1) V_{DD} is V_{DD} when GPIO is normal IO, and V_{DD} is V_{HV} when GPIO is HV high voltage IO.

As shown in Figure 6-1, the IO port structure is shown. Each pin has two protection diodes inside the chip. The IO port can be divided into input and output driver modules. The input driver has optional weak pull-up and pull-down resistors, which can be connected to analog input peripherals such as ADC; if the input is to a digital peripheral, it needs to go through a TTL Schmitt trigger and then be connected to a GPIO input register or other multiplexing peripherals. The output driver has a pair of MOS tubes, and the IO port can be configured as a push-pull output by configuring the upper and lower MOS tubes; the output driver can also be configured internally to be controlled by GPIO or by other multiplexed peripherals.

6.2.2 GPIO Initialization Function

Just after reset, the GPIO port runs in the initial state. At this time, most IO ports run in the floating input state. For specific initialization functions, please refer to the relevant chapters of the pin description.

6.2.3 External Interrupts

All GPIO ports can be configured with external interrupt input channels, but an external interrupt input channel can only be mapped to at most one GPIO pin, and the serial number of the external interrupt channel must be consistent with the bit number of the GPIO port, such as PA1 (or PB1) can only be mapped to EXTI1, and EXTI1 can only accept the mapping of one of PA1 and PB1. Both parties have a one-to-one relationship.

6.2.4 Alternate Functions

It is important to note that using the alternate function.

• To use the alternate function in the input direction, the port must be configured in alternate input mode, and

the pull-down settings can be set according to actual needs.

- To use the alternate function in the output direction, the port must be configured in alternate output mode.
- For bidirectional alternate function, the port must be configured in alternate output mode, when the driver is configured in floating input mode

The same I/O port may have multiple peripherals alternate to this pin, so in order to maximize the space for each peripheral, the alternate pins of peripherals can be remapped to other pins in addition to the default alternate pins, avoiding the occupied pins.

6.2.5 Locking Mechanism

The locking mechanism locks the configuration of the I/O port. After a specific write sequence, the selected I/O pin configuration will be locked and cannot be changed until the next reset.

6.2.6 Input Configuration

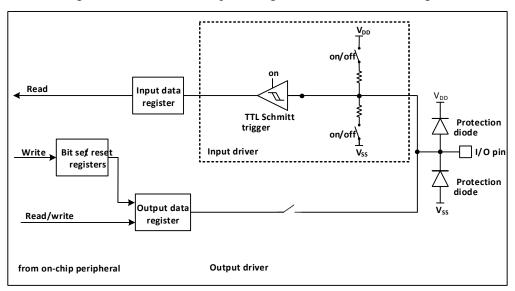

Figure 6-2 GPIO module input configuration structure block diagram

When the IO port is configured in input mode, the output driver is disconnected, the input pull-up and pull-down are selectable, and no alternate functions or analogue inputs are connected. The data on each IO port is sampled at each HB clock into the input data register and the level status of the corresponding pin is obtained by reading the corresponding bit in the input data register.

6.2.7 Output Configuration

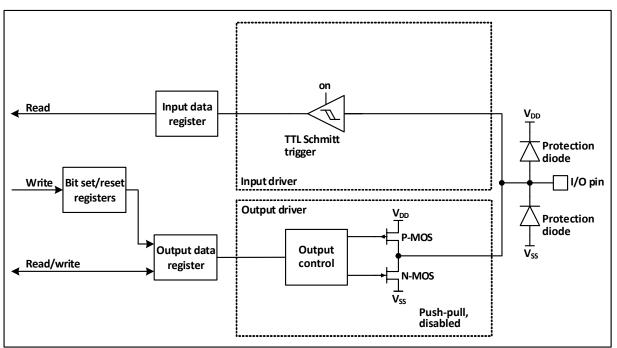

Figure 6-3 GPIO module output configuration structure block diagram

When the IO port is configured in output mode, a pair of MOS in the output driver is configured in push-pull mode, and the alternate function is not used. The input driver's pull-up and pull-down resistors are disabled, the TTL Schmitt trigger is activated and the levels appearing on the IO pins will be sampled into the input data registers at each HB clock, so reading the input data registers will give the IO status and access to the output data registers will give the last written value.

6.2.8 Alternate Function Configuration

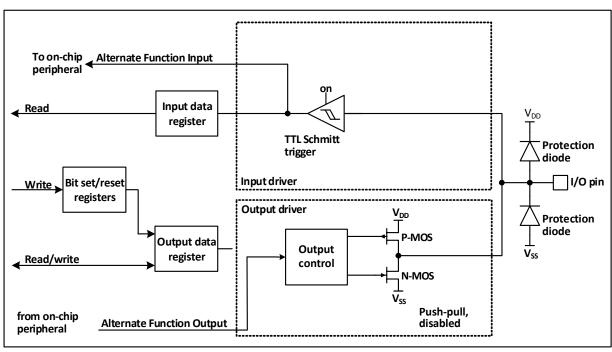

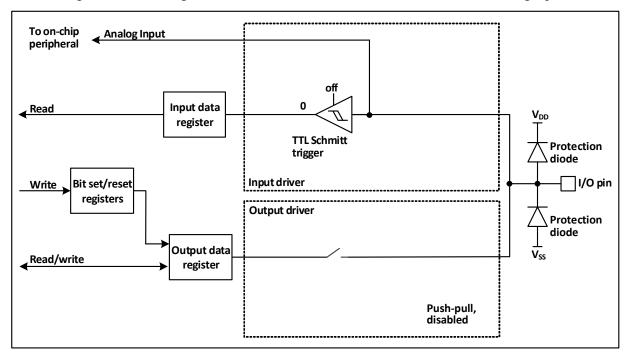

Figure 6-4 The structure of GPIO module when it is alternate by other peripherals

When alternate is enabled, the output drivers are enabled, configured in push-pull mode, or automatically configured in open-drain mode if used for I2C, the Schmitt trigger is turned on, the input and output lines of the alternate function are connected, but the output data registers are disconnected, the levels present on the IO pins will be sampled into the input data registers at each HB clock, and reading the input data registers will give the current status of the IO port; in push-pull mode, reading the output data registers will give the last written value.

6.2.9 Analog Input Configuration

Figure 6-5 The configuration structure when the GPIO module is used as an analog input

6.2.10 GPIO Settings for Peripherals

The following table recommends the corresponding GPIO port configuration for each peripheral pin.

| TIM1 | Configuration | GPIO configuration |
|-----------|----------------------------------|----------------------------|
| TIM1 CHx | Input capture channel x | Floating input |
| | Output compare channel x | Push-pull alternate output |
| TIM1_CHxN | Complementary output channels x | Push-pull alternate output |
| TIM1_BKIN | Brake input | Floating input |
| TIM1_ETR | Externally triggered clock input | Floating input |

| Bit | Name | Access | Description | Reset value |
|---------|----------|--------|--|-------------|
| [31:17] | Reserved | RO | Reserved | 0 |
| 16 | LCKK | RW | Lock key, which can be locked by a specific sequence of writes, but it can be read out at any time. When it reads 0, it means that the lock is not in effect, and when it reads 1, it means that the lock is in effect. The writing sequence of the lock key is: write 1- write 0-write 1-read 0-read 1. The last step is not necessary, but it can be used to confirm that the lock key has been activated. Any errors while writing the sequence will not activate the lock, and the value of LCK[7:0] cannot be changed while the sequence is being written. Once the lock is in effect, the port's configuration cannot be changed until the next reset. | 0 |
| [15:0] | LCKy | RW | (y=0-15), when these bits are 1, it means locking the configuration of the corresponding port. These bits can only be changed before LCKK is unlocked. The locked configuration refers to the configuration registers GPIOx_CFGLR and GPIOx_CFGHR. | 0 |

Note: After the LOCK sequence is executed for the corresponding port bit, the configuration of the port bit will not be changed again until the next system reset.

6.3.2 AFIO Register Description

Unless otherwise specified, AFIO registers must be operated as words (operate these registers with 32 bits).

Chapter 7 Direct Memory Access Control (DMA)

The Direct Memory Access (DMA) controller provides a high-speed means of data transfer between peripherals and memory or between memory and memory without CPU intervention, data can be moved quickly through the DMA to save CPU resources for other operations.

Each channel of the DMA controller is dedicated to managing requests for memory access from one or more peripherals. There is also an arbiter to co-ordinate priorities between the channels.

7.1 Main Features

- Multiple independently configurable channels
- Each channel is directly connected to a dedicated hardware DMA request and supports software triggering
- Support Buffer management with loop
- Request priority between multiple channels can be set by software programming (very high, high, medium and low) and priority setting is determined by the channel number when equal (the lower the channel number the higher the priority)
- Support peripheral-to-memory, memory-to-peripheral, and memory-to-memory transfers
- Flash memory, SRAM, peripheral SRAM and HB peripherals can be used as access sources and targets
- Programmable number of data transfer bytes: up to 65535

7.2 Function Description

7.2.1 DMA Channel Processing

1) Arbitration priority

DMA requests generated by multiple independent channels are fed to the DMA controller via a logical or structure, and only one channel request is currently responded to. An arbiter inside the module selects the peripheral/memory access to be initiated based on the priority of the channel request.

In software management, the application can configure the priority level for each channel independently by setting the PL[1:0] bits of the DMA_CFGRx register, including 4 levels: highest, high, medium and low. When the software setting levels are the same between channels, the module will be selected according to a fixed hardware priority, with the lower channel number having a higher priority than the higher one.

2) DMA configuration

When the DMA controller receives a request signal, it accesses the requested peripheral or memory and establishes a data transfer between the peripheral or memory and the memory. It consists of the following 3 main operation steps.

- (1) Fetch data from the memory address indicated by the Peripheral Data Register or the Current Peripheral/Memory Address Register. The start address for the first transfer is the peripheral base address or memory address specified by the DMA_PADDRx or DMA_MADDRx registers.
- (2) Store data to the memory address indicated by the Peripheral Data Register or the Current Peripheral/Memory Address Register, and the start address for the first transfer is the peripheral base address or memory address specified by the DMA_PADDRx or DMA_MADDRx registers.
- (3) Performs a decrement operation of the value in the DMA_CNTRx register, which indicates the number of operations currently outstanding for transfer.

Each channel includes 3 types of DMA data transfer methods.

- Peripheral to memory (MEM2MEM=0, DIR=0)
- Memory to peripheral (MEM2MEM=0, DIR=1)
- Memory to memory (MEM2MEM=1)

Note: The memory-to-memory mode does not require a peripheral request signal. After configuring this mode (MEM2MEM=1), the channel is turned on (EN=1) to start data transfer. This mode does not support cyclic mode.

The configuration process is as follows.

- Set the first address of the peripheral register or the memory data address in the memory-to-memory mode (MEM2MEM=1) in the DMA_PADDRx register. This address will be the source or destination address for data transfer when a DMA request occurs.
- 2) Set the memory data address in the DMA_MADDRx register. When a DMA request occurs, the transferred data will be read from or written to this address.
- 3) Set the amount of data to be transferred in the DMA_CNTRx register. This value is decremented after each data transfer.
- 4) Set the priority of the channel in the PL[1:0] bits of the DMA_CFGRx register.
- 5) Set the direction of data transfer, cyclic mode, incremental mode for peripheral and memory, data width for peripheral and memory, transfer halfway, transfer complete, and transfer error interrupt enable bits in the DMA_CFGRx register.
- 6) Set the ENABLE bit of the DMA_CCRx register to start channel x.

Note: The DMA_PADDRx/DMA_MADDRx/DMA_CNTRx registers and the direction of data transfer (DIR), cyclic mode (location), and incremental mode of peripherals and memory (MINC/PINC) control bits in the DMA_CFGRx register can be configured to write only when the DMA channel is turned off.

3) Circular mode

Setting CIRC position 1 of the DMA_CFGRx register enables the cyclic mode function for channel data transfers. In cyclic mode, when the number of data transfers becomes 0, the contents of the DMA_CNTRx register are automatically reloaded to its initial value, and the internal peripheral and memory address registers are reloaded to the initial address values set by the DMA_PADDRx and DMA_MADDRx registers, and DMA operation will continue until the channel is turned off or the DMA mode is turned off.

4) DMA processing status

- Transfer half: It corresponds to the hardware setting of HTIFx bit in DMA_INTFR register. The DMA transfer bytes half flag will be generated when the number of DMA transfers is reduced to less than half of the initial set value, and an interrupt will be generated if HTIE is set in the DMA_CCRx register. The hardware uses this flag to alert the application that it can prepare for a new round of data transfers.
- Transfer completion: corresponds to the hardware setting of the TCIFx bit in the DMA_INTFR register. When the number of DMA transfer bytes decreases to 0, the DMA transfer completion flag will be generated, and if TCIE is set in the DMA_CCRx register, an interrupt will be generated.
- Transfer error: corresponds to a hardware set of the TEIFx bit in the DMA_INTFR register. Reading and writing a reserved address area will generate a DMA transfer error. At the same time the module hardware will automatically clear the EN bit of the DMA_CCRx register corresponding to the channel where the error occurred, and the channel is turned off. If TEIE is set in the DMA_CCRx register, an interrupt will be generated.

When the application queries the DMA channel status, it can first access the GIFx bit of the DMA_INTFR register

to determine which channel is currently experiencing a DMA event, and then process the specific DAM event content for that channel.

7.2.2 Programmable Total Data Transfer Size/Data Bit Width/Alignment

The total size of the data to be transferred per DMA channel round is programmable up to 65535 times, and the number of pending transfer bytes is indicated in the DMA_CNTRx register. At EN=0, the set value is written, and at EN=1 when the DMA transfer channel is turned on, this register becomes a read-only attribute with a decreasing value after each transfer.

The transferred data fetch values of peripherals and memories support the address pointer auto-increment function with programmable pointer increments. The first transmitted data address they access is stored in the DMA_PADDRx and DMA_MADDRx registers.By setting the PINC bit or MINC position 1 of the DMA_CFGRx register, the peripheral address self-increment mode or memory address self-increment mode can be enabled, respectively. PSIZE[1:0] sets the peripheral address fetch data size and address self-increment size. MSIZE[1:0] sets the memory address to take the data size and address self-increasing small, including three choices: 8-bit, 16-bit, 32-bit. The specific data transfer methods are listed in the following table.

| Source bit width | Objectives bit width | Transmission number | Source: address/data | Target: address/data | Transfer operations |
|---------------------|-------------------------|------------------------|--|--|---|
| 8 | 8 | 4 | 0x00/B0 0x01/B1 0x02/B2 0x03/B3 | 0x00/B0 0x01/B1 0x02/B2 0x03/B3 | |

|--------|----------|--------|---|-------------|
| [31:0] | MA[31:0] | RW | The memory data address, which serves as the source or destination address for data transfers. When MSIZE[1:0]='01' (16 bits), the module automatically ignores bit0, and the operation address is automatically 2-byte aligned; when MSIZE[1:0]='10' (32 bits), the module automatically ignores bit[1:0], and the operation address is automatically 4-byte aligned. | 0 |

Note: This register can only be changed when EN=0 *and cannot be written when* EN=1*.*

Chapter 8 Analog-to-digital Converter (ADC)

The ADC module contains one 10-bit successive approximation ADC, allowing an input clock of up to 12MHz. Supports 15 external channels and 1 internal signal source sampling source. It can complete single conversion, continuous conversion of channels, automatic scanning mode between channels, intermittent mode, external trigger mode, trigger delay and other functions. The analog watchdog function can be used to monitor whether the channel voltage is within the threshold range.

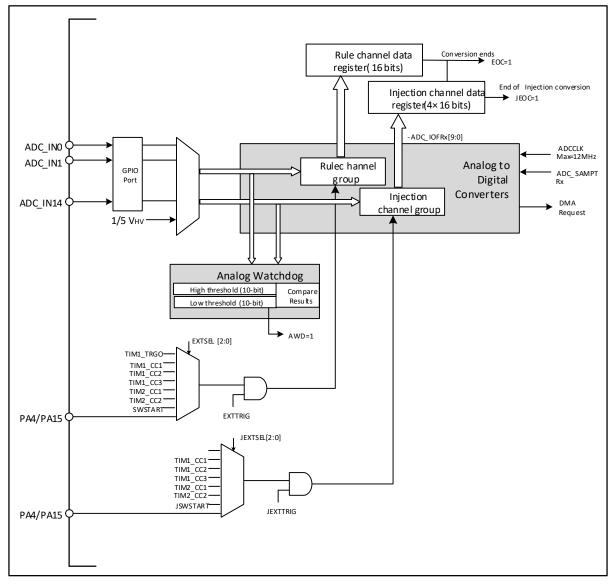

8.1 Main Features

- 10-bit resolution
- Supports 15 external channels and 1 internal signal sources for sampling
- Multiple sampling conversion methods for multiple channels: single, continuous, scan, trigger, intermittent, etc.
- Data alignment modes: left-aligned, right-aligned
- Sampling time can be programmed separately by channel
- Both rule conversion and injection conversion support external triggering
- Analog watchdog to monitor channel voltage, self-calibration function
- ADC channel input range: $GND \le V_{IN} \le V_{33}$
- Trigger delay

8.2 Functional Description

8.2.1 Module Structure

8.2.2 ADC Configuration

1) Module power-up

An ADON bit of 1 in the ADC_CTLR2 register indicates that the ADC module is powered up. When the ADC module enters the power-up state (ADON=1) from the power-down mode (ADON=0), a delay period t_{STAB} is required for the module stabilization time. After that, the ADON bit is written to 1 again and is used as the start signal for software to start the ADC conversion. By clearing the ADON bit to 0, the current conversion can be terminated and the ADC module placed in power-down mode, a state in which the ADC consumes almost no power.

2) Sampling clock

The module's register operation is based on the HBCLK (HB bus) clock, and the clock reference ADCCLK of its conversion unit is divided by the ADCPRE field configuration of the RCC_CFGR0 register. For detailed

information, refer to the data sheet CH641DS0.

3) Channel configuration

The ADC module provides 14 channel sampling sources. They can be configured into two types of conversion groups: regular groups and injection groups. to achieve a group conversion consisting of a series of conversions in any order on any number of channels.

Conversion group:

- Rule group: consists of up to 16 conversions. The rule channels and their conversion order are set in the ADC_RSQRx register. The total number of conversions in the rule group should be written to L[3:0] in the ADC_RSQR1 register.
- Injection group: consists of up to 4 conversions. The injection channels and the order of their conversions are set in the ADC_ISQR register. The total number of conversions in the injection group should be written in JL[1:0] of the ADC ISQR register.

Note: (1) If the ADC_RSQRx or ADC_ISQR registers are changed during conversion, the current conversion is terminated and a new start signal is sent to the ADC to convert the newly selected group. (2) ADC IN9 connects to the output of QII OP.

1 internal channel:

- 1/5 divider of V_{HV} voltage: Connect the ADC_IN15 channel and the internal channel sampling time is recommended to be set above 40us.
- 4) Calibration

The ADC has a built-in self-calibration mode. The accuracy error caused by changes in the internal capacitor bank can be greatly reduced through the calibration process. During calibration, an error correction code is calculated on each capacitor, which is used to eliminate errors produced on each capacitor in subsequent conversions.

Initialize the calibration register by writing the RSTCAL bit of the ADC_CTLR2 register to 1, and wait for the RSTCAL hardware to clear to 0 to indicate that the initialization is complete. Set the CAL bit to start the calibration function. Once the calibration is completed, the hardware will automatically clear the CAL bit and store the calibration code in ADC_RDATAR. After that normal conversion functions can begin. It is recommended to perform an ADC calibration when the ADC module is powered on.

Note: Before starting calibration, you must ensure that the ADC module is in the power-on state (ADON=1) for at least two ADC clock cycles.

5) Programmable sampling time

The ADC uses several ADCCLK cycles to sample the input voltage. The number of sampling cycles for a channel can be changed using the SMPx[1:0] bits in the ADC_SAMPTR1 and ADC_SAMPTR2 registers. Each channel can be sampled separately using a different time.

The total conversion time is calculated as follows.

 $T_{CONV} =$ sampling time + 11 T_{ADCCLK}

The ADC's rule channel conversion supports the DMA function. The value of the rule channel conversion is stored in a data-only register, ADC_RDATAR. To prevent the data in ADC_RDATAR register from being fetched in time when multiple rule channels are converted in succession, the DMA function of ADC can be enabled. The hardware will generate a DMA request at the end of the conversion of a rule channel (EOC set) and transfer the converted data from the ADC_RDATAR register to the user-specified destination address.

After the channel configuration of the DMA controller module is completed, write DMA position 1 of the

ADC_CTLR2 register to enable the DMA function of the ADC.

Note: Injection group conversion does not support DMA function.

6) Data alignment

The ALIGN bit in the ADC_CTLR2 register selects the alignment of the ADC converted data storage. 12-bit data supports left-aligned and right-aligned modes.

The data register ADC_RDATAR of the rule group channel holds the actual converted 12-bit digital value; while the data register ADC_IDATARx of the injection group channel is the actual converted data minus the value written after the offset defined in the ADC_IOFRx register, there will be positive and negative cases, so there are sign bits (SIGNB).

8.2.3 External Trigger Source

The start event of ADC conversion can be triggered by external events. If the EXTTRIG or JEXTTRIG bits of the ADC_CTLR2 register are set, conversions of rule group or injection group channels can be triggered by external events, respectively. At this time, the configuration of the EXTSEL[2:0] and JEXTSEL[2:0] bits determines the external event source of the rule group and injection group. ADC_TRIG_SEL0-4 bits configure the comparison event of TIM1 and TIM2 as an external trigger event for the injection group or the rule group.

Note: When the external trigger signal is selected for ADC rule or injection conversion, only its rising edge can initiate conversion.

8.2.4 Conversion Mode

| AD | OC CTLR | and ADC CTLR2 r | ADC conversion mode | | | | |
|------|---------|--|---------------------|--|---|--|--|
| CONT | SCAN | DISCEN/JDISCEN | JAUTO | Start event | ADC conversion mode | | |
| | 0 | 0 | 0 | ADON position 1 External trigger method | Single single-channel mode: A rule channel performs a single conversion. Single single-channel mode: A single conversion is performed on one of the rule channels or injection channels. | | |
| | 1 | 0 | 0 | ADON position 1 or external trigger method | Single scan mode: performs a single conversion of all selected rule group channels (ADC_RSQRx) or all injection group channels (ADC_ISQR) one by one in sequence. Trigger injection method: When the rule group channel conversion process can be inserted into the injection group channel all conversion, and then continue the rule group channel conversion afterwards; but the rule group channel conversion will not be inserted when converting the injection group channel. | | |
| 0 | | | 1 | ADON position 1 or external trigger method | Single scan mode: performs a single conversion of all selected rule group channels (ADC_RSQRx) or all injection group channels (ADC_ISQR) one by one in sequence. Automatic injection method: After the rule group channel is converted, the injection group channel is automatically converted. <i>Note: External trigger signals injected into the</i> <i>channel are not allowed during the conversion</i> <i>process.</i> | | |
| | 0 | 1 (DISCEN and JDISCEN cannot be 1 at the same time) | 0 | External trigger method | Single intermittent mode: Each time an event is started, a short sequence (DISCNUM[2:0] defined number) of channel number transitions is executed and cannot be restarted until all selected channel transitions are completed. <i>Note: The DISCEN and JDISCEN control bits</i> <i>are selected for the rule group and injection</i> <i>group respectively, and the intermittent mode</i> <i>cannot be configured for the rule group and</i> <i>injection group at the same time.</i> | | |
| | | | 1 | - | Disable this mode. | | |
| | 1 | 1 | Х | - | No such mode. | | |
| | 0 | 0 | 0 | ADON | Continuous single channel/scan mode: repeat a | | |
| 1 | 1 | 0 | 0 | position 1 or external trigger | new round of transitions at the end of each round until CONT clears 0 to terminate. | | |

| method | |
|--------|--|
|--------|--|

Note: The external trigger events for rule groups and injection groups are different, and the 'ACON' bit can only initiate rule group channel conversion, so the initiation events for rule group and injection group channel conversion are independent.

1) Single single-channel conversion mode

In this mode, only one conversion is executed for the current 1 channel. This mode performs conversion for the channel that is sorted 1st in the rule group or injection group, where it is initiated by setting ADON position 1 of the ADC_CTLR2 register (for rule channels only) or can be initiated by external trigger (for rule channels or injection channels). Once the conversion of the selected channel is completed it will.

If the conversion is for a rule group channel, the conversion data is stored in the 16-bit ADC_RDATAR register, the EOC flag is set, and an ADC interrupt is triggered if the EOCIE bit is set.

If the conversion is for an injection group channel, the conversion data is stored in the 16-bit ADC_IDATAR1 register, the EOC and JEOC flags are set, and an ADC interrupt is triggered if the JEOCIE or EOCIE bit is set.

2) Single scan mode conversion

The ADC scan mode is entered by setting the SCAN bit of the ADC_CTLR1 register to 1. This mode is used to scan a group of analog channels and perform a single conversion for all channels selected by ADC_RSQRx register (for regular channels) or ADC_ISQR (for injection channels) one by one, and the next channel in the same group is converted automatically when the current channel conversion is finished.

In the scan mode, there is a subdivision into triggered injection mode and automatic injection mode depending on the status of the JAUTO bit.

• Trigger injection

JAUTO bit is 0. When the trigger event of injection group channel conversion occurs during the scanning of rule group channels, the current conversion is reset and the sequence of injection channels is performed in a single scan, and the last interrupted rule group channel conversion is resumed after all selected injection group channel scanning conversions are completed.

If a rule channel start event occurs while the injection group channel sequence is currently being scanned, the injection group conversion is not interrupted, but the rule sequence conversion is executed again after the injection sequence conversion is completed.

Note: When using triggered injection conversions, you must ensure that the interval between triggered events is longer than the injection sequence. For example, if the overall time to complete the conversion of the injection sequence takes 28 ADCCLK, then the minimum value of the event interval to trigger the injection channel is 29 ADCCLK.

• Auto-injection

The JAUTO bit is set to 1, and conversion of the selected channel of the injection group is performed automatically after scanning all the channels selected by the rule group for conversion. This approach can be used to convert up to 20 conversion sequences in the ADC_RSQRx and ADC_ISQR registers.

In this mode, external triggering of the injection channel must be disabled (JEXTTRIG=0).

Note: When the ADC clock prescaler coefficient (ADCPRE[1:0]) is 4 to 8, when switching from regular conversion to injection sequence or from injection conversion to regular sequence, 1 ADCCLK interval will be automatically inserted; When the ADC clock prescaler factor is 2, there is a delay of 2 ADCCLK intervals.

3) Single intermittent mode conversion

The intermittent mode of the rule group or injection group is entered by setting the DISCEN or JDISCEN bit of the

ADC_CTLR1 register to 1. This mode differs from scanning a complete set of channels in scan mode, but divides a set of channels into multiple short sequences, and each external trigger event will perform a short sequence of scan transitions.

The length n (n<=8) of the short sequence is defined in DISCNUM[2:0] of the ADC_CTLR1 register. When DISCEN is 1, it is the discontinuous mode of the rule group, and the total length to be converted is defined in L[3: 0] of the ADC_RSQR1 register; when JDISCEN is 1, it is the discontinuous mode of the injection group, and the total length to be converted is defined in JL[1:0] of the ADC_ISQR register. You cannot set both a rule group and an injection group to discontinuous mode at the same time.

Example of rule group intermittent mode.

DISCEN=1, DISCNUM[2:0]=3, L [3:0]=8, channels to be converted = 1, 3, 2, 5, 8, 4, 10, 6

The 1st external trigger: conversion sequence is: 1, 3, 2

The 2nd external trigger: conversion sequence is: 5, 8, 4

The 3rd external trigger: conversion sequence is: 10, 6, while generating EOC events

The 4th external trigger: conversion sequence is: 1, 3, 2

Examples of intermittent patterns injected into groups.

JDISCEN=1, DISCNUM[2:0]=1, JL[1:0]=3, channel to be converted=1, 3, 2

The 1st external trigger: conversion sequence is: 1

The 2nd external trigger: the conversion sequence is: 3

The 3rd external trigger: conversion sequence is: 2, generating both EOC and JEOC events

The 4th external trigger: conversion sequence is: 1

Note: 1. When converting a rule group or injection group in intermittent mode, the conversion sequence does not automatically start from the beginning when it ends. When all subgroups have been converted, the next trigger event starts the conversion of the first subgroup.

2. You cannot use auto-injection (JAUTO=1) and intermittent mode at the same time.

3. You cannot set intermittent mode for both rule groups and injection groups, and intermittent mode can only be used for a group of conversions.

4) Continuous conversion

In the continuous conversion mode, another conversion is started as soon as the previous ADC conversion is completed. The conversion will not stop on the last channel of the selection group, but will continue conversion from the first channel of the selection group again. The startup events in this mode include external trigger events and the ADON bit is set to 1. After setting the startup, the CONT bit needs to be set to 1.

If a regular channel is converted, the conversion data is stored in the ADC_RDATAR register, the conversion end flag EOC is set, and if EOCIE is set, an interrupt is generated.

If an injection channel is converted, the conversion data is stored in the ADC_IDATARx register, the injection conversion end flag JEOC is set, and if JEOCIE is set, an interrupt is generated.

8.2.5 Analog Watchdog

The AWD analog watchdog status bit is set if the analog voltage being converted by the ADC is below the low threshold or above the high threshold. The threshold settings are located in the lowest 12 valid bits of the ADC_WDHTR and ADC_WDLTR registers. The AWDIE bit of the ADC_CTLR1 register is set to allow the corresponding interrupt to be generated.

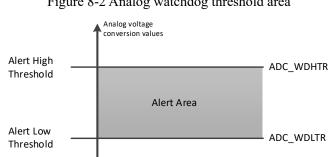

Figure 8-2 Analog watchdog threshold area

Configure the AWDSGL, AWDEN, JAWDEN and AWDCH[4:0] bits of the ADC_CTLR1 register to select the channel for analog watchdog alerting, as related in the following table.

| Analog Watchdog alert | | ADC_CTLI | R1 register control | bit |
|-----------------------------------|--------|----------|---------------------|---------------------------------|
| channel | AWDSGL | AWDEN | JAWDEN | AWDCH[4:0] |
| No vigilance | Ignore | 0 | 0 | Ignore |
| All injection channels | 0 | 0 | 1 | Ignore |
| All rule channels | 0 | 1 | 0 | Ignore |
| All injection and rule channels | 0 | 1 | 1 | Ignore |
| Single injection channel | 1 | 0 | 1 | Determine the channel number |
| Single rule channel | 1 | 1 | 0 | Determine the channel number |
| Single injection and rule channel | 1 | 1 | 1 | Determine the channel number |

8.3 Register Description

Table 8-7 ADC-related registers list

| Bit | Name | Access | Description | Reset value |
|---------|-----------|--------|---|-------------|
| [31:22] | Reserved | RO | Reserved | 0 |
| [21:20] | JL[1:0] | RW | Inject the number of channels to be converted in the channel conversion sequence. 00-11: 1-4 conversions. | 0 |
| [19:15] | JSQ4[4:0] | | The number of the 4th conversion channel in the injection sequence (0-15). Note: Software writes and assigns the channel number (0-15) as the 4th in the sequence to be converted. | 0 |
| [14:10] | JSQ3[4:0] | RW | The number of the 3th conversion channel in the injection sequence (0-15). | 0 |
| [9:5] | JSQ2[4:0] | RW | The number of the 2th conversion channel in the injection sequence (0-15). | 0 |

| [4:0] | JSQ1[4:0] | RW | The number of the 1th conversion channel in the injection sequence (0-15). | 0 |
|-------|-----------|----|--|---|
|-------|-----------|----|--|---|

Note: Unlike the regular conversion sequence, if the length of JL[1:0] is less than 4, the sequence order of conversion starts from (4 - JL).

For example, when JL[1:0]=3 (4 injected transitions in the sequencer), the ADC will convert channels in the following order: JSQ1[4:0], JSQ2[4:0], JSQ3[4:0], and JSQ4[4:0];

When JL[1:0]=2 (3 injected transitions in the sequencer), the ADC will convert the channels in the following order: JSQ2[4:0], JSQ3[4:0] and JSQ4[4:0];

When JL[1:0]=1 (2 injected conversions in the sequencer), the ADC converts the channels in the following order: *first JSQ3[4:0], then JSQ4[4:0];*

When JL[1:0] = 0 (1 injection conversion in the sequencer), the ADC will convert only the JSQ4[4:0] channels.

If ADCx_ISQR[21:0]=10 00111 00011 00111 00010, the ADC will convert channels in the following order: JSQ2[4:0], JSQ3[4:0], and JSQ4[4:0], indicating that the scan conversions are performed in the following channel order: 7, 3, 7.

Chapter 9 Advanced-control Timer (ADTM)

The Advanced-control timer Module contains one powerful 16-bit auto-reload timer TIM1, which can be used to measure pulse width or generate pulses, PWM waves, etc. It is used in motor control, power supply, etc.

9.1 Main Features

The main features of the advanced-control timer TIM1 include.

- 16-bit auto-reload counter supporting incremental counting mode, decremental counting mode and incremental and decremental counting mode.
- 16-bit prescaler with dynamically adjustable crossover coefficients from 1 to 65536.
- Support 3 independent comparison capture channels.
- Each comparison capture channel supports multiple operating modes, such as: input capture, output comparison, PWM generation and single pulse output.
- Support complementary outputs with programmable dead time;
- Support external signals to control the timer.
- Support updating the timer after a defined period using a repeat counter.
- Support resetting the timer or placing it in the OK state using the brake signal.
- Support the use of DMA in multiple modes.
- Support incremental encoders.
- Support cascading and synchronization between timers.

9.2 Principle and Structure

This section deals with the internal construction of advanced-control timers.

9.2.1 Overview

As shown in Figure 9-1, the structure of the advanced-control timer can be roughly divided into 3 parts, namely the input clock part, the core counter part and the compare capture channel part.

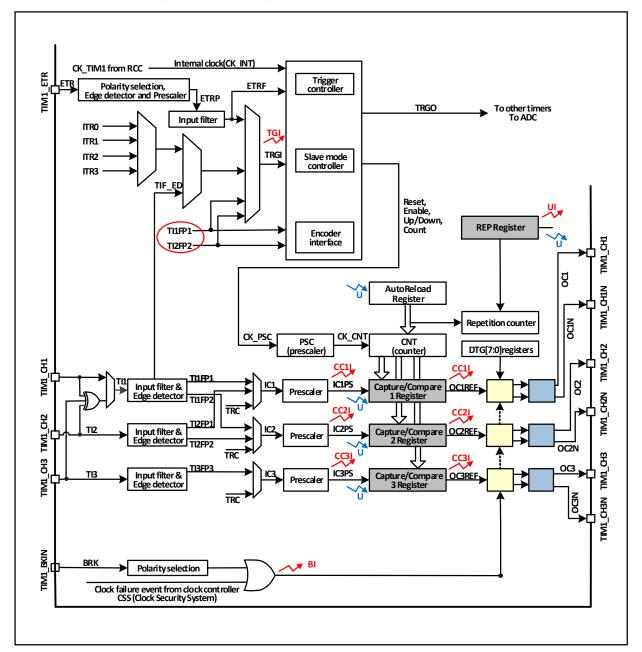

The advanced-control timer can be clocked from the HB bus clock (CK_INT), from an external clock input pin (TIMx_ETR), from other timers with clock output (ITRx), or from the input of the compare capture channel (TIMx_CHx). These input clock signals become the CK_PSC clock after various set filtering and dividing operations and are output to the core counter section. In addition, these complex clock sources can also be output as TRGO to other peripherals such as timers and ADCs.

The core of the advanced timer is a 16-bit counter (CNT). After CK_PSC is divided by the prescaler (PSC), it becomes CK_CNT and is output to CNT. CNT supports up counting mode, down counting mode and up and down counting mode, and has an automatic reload value register (ATRLR) in each count After the cycle ends, the CNT is reloaded with the initial value. There is also an auxiliary counter that counts the number of times ATRLR reloads the initial value for CNT. When the number reaches the number set in the repetition count value register (RPTCR), a specific event can be generated.

The core of the advanced timer is a 16-bit counter (CNT). After CK_PSC is divided by the prescaler (PSC), it becomes CK_CNT and is output to CNT. CNT supports up counting mode, down counting mode and up and down counting mode, and has an automatic reload value register (ATRLR) in each count After the cycle ends, the CNT is reloaded with the initial value. There is also an auxiliary counter that counts the number of times ATRLR reloads

the initial value for CNT. When the number reaches the number set in the repetition count value register (RPTCR), a specific event can be generated.

The advanced timer has three sets of compare capture channels. Each set of compare capture channels can input pulses from its own pins and can also output waveforms to the pins. That is, the compare capture channels support input and output modes. The input of each channel of the compare capture register supports operations such as filtering, frequency division, and edge detection, supports mutual triggering between channels, and can also provide a clock for the core counter CNT. Each compare capture channel has a set of compare capture registers (CHxCVR) that support comparison with the main counter (CNT) and output pulses.

9.2.2 Clock Input

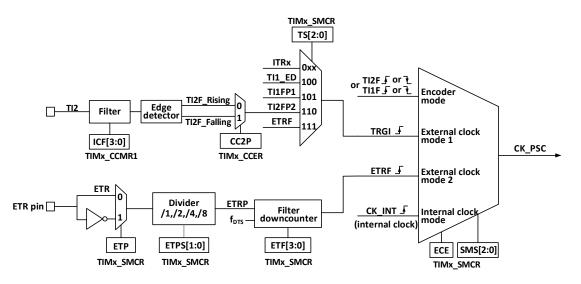

Figure 9-2 Block diagram of CK_PSC source for advanced-control timer

The advanced-control timer CK_PSC has many clock sources and can be divided into 4 categories.

- 1) Route of external clock pin (ETR) input clock: $ETR \rightarrow ETRP \rightarrow ETRF$.
- 2) Internal HB clock input route: CK_INT.
- 3) Route from the comparison capture channel pin (TIMx_CHx): TIMx_CHx → TIx → TIxFPx, this route is also used in encoder mode.
- 4) Inputs from other internal timers: ITRx.

The actual operation can be divided into 4 categories by determining the choice of input pulse for the SMS of the CK PSC source.

- 1) Selection of the internal clock source (CK_INT).
- 2) External clock source mode 1.
- 3) External clock source mode 2.
- 4) Encoder mode.

All 4 clock source sources mentioned above can be selected by these 4 operations.

9.2.2.1 Internal Clock Source (CK_INT)

If the SMS field is held at 000b to start the advanced-control timer, then it is the internal clock source (CK_INT) that is selected as the clock. At this point CK_INT is CK_PSC.

9.2.2.2 External Clock Source Mode1

When the SMS domain is set to 111b, external clock source mode 1 is enabled. When external clock source 1 is enabled, TRGI is selected as the source of CK_PSC. it is worth noting that the source of TRGI also needs to be selected by configuring the TS domain. the TS domain can select the following types of pulses as clock sources.

- 1) Internal trigger (ITRx, x is 0,1,2,3).
- 2) Comparison of the signal after capturing channel 1 through the edge detector (TI1F_ED).
- 3) Comparison of signals TI1FP1, TI2FP2 of the capture channel.
- 4) The signal ETRF from the external clock pin input.

9.2.2.3 External Clock Source Mode2

Use external trigger mode 2 to count on every rising or falling edge of the external clock pin input. When the ECE position is set, the external clock source mode 2 is used. when using the external clock source mode 2, ETRF is selected as CK_PSC. the ETR pin becomes ETRP after passing through the optional inverter (ETP), divider (ETPS), and then ETRF after passing through the filter (ETF).

With the ECE position bit and the SMS set to 111b, this is equivalent to the TS selecting ETRF as an input.

9.2.2.4 Encoder Mode

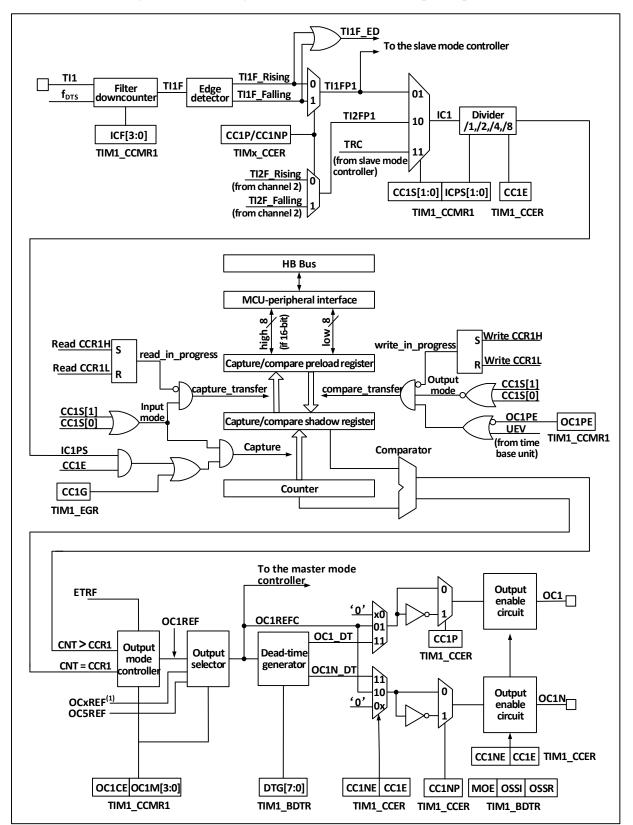

Setting the SMS to 001b, 010b, 011b will enable the encoder mode. Enabling encoder mode allows you to select a specific level in TI1FP1 and TI2FP2 to signal the output with another jump edge as the signal. This mode is used when an external encoder is used. Refer to Section 9.3.9 for specific functions.

9.2.3 Counters and Peripherals

CK_PSC is input to the prescaler (PSC) for frequency division. PSC is 16 bits, and the actual frequency division coefficient is equivalent to the value of R16_TIM1_PSC + 1. CK_PSC will become CK_INT after passing through PSC. Changing the value of R16_TIM1_PSC will not take effect in real time, but will be updated to PSC after the update event. Update events include clearing and resetting the UG bit. The core of the timer is a 16-bit counter (CNT). CK_CNT will eventually be input to CNT. CNT supports up counting mode, down counting mode and up and down counting mode, and has an automatic reload value register (ATRLR) in each count. After the cycle ends, the CNT is reloaded with initial values. There is also an auxiliary counter that records the number of times ATRLR reloads the initial value for CNT. When the number of times set in the repetition count value register (RPTCR) is reached, a specific event can be generated.

9.2.4 Compare/Capture Channels and Peripherals

The compare capture channel is the main component for the timer to implement complex functions. Its core is the compare capture register, supplemented by digital filtering of the peripheral input part, frequency division and interchannel multiplexing, and the comparator and output control of the output part.

The structure block diagram of the compare/capture channel is shown in Figure 9-3. The signal is input from the channel x pin and optionally made as TIx (the source of TI1 can be more than just CH1, see the structure block diagram of timer 9-1), TI1 is passed through the filter (ICF[3:0]) to generate TI1F, and then divided into TI1F_Rising and TI1F_Falling through the edge detector, these two signals are selected (CC1P) to generate TI1FP1, TI1FP1 and

TI2FP1 from channel 2 are sent together to CC1S to select to become IC1, which is sent to the compare capture register after ICPS dividing.

The compare capture register consists of a preload register and a shadow register, and the read/write process operates only on the preload register. In capture mode, the capture occurs on the shadow register and is then copied to the preload register; in compare mode, the contents of the preload register are copied to the shadow register, and then the contents of the shadow register are compared to the core counter (CNT).

9.3 Function and Implementation

The implementation of advanced timer complex functions is achieved by operating the timer's comparison capture channel, clock input circuit, counter and peripheral parts. The clock input to the timer can come from multiple clock sources including the input to the compare capture channel. The operation of comparing the capture channel and clock source selection directly determines its function. The compare capture channel is bidirectional and can work in input and output modes.

9.3.1 Input Capture Mode

Input capture mode is one of the basic functions of the timer. The principle of the input capture mode is that when a certain edge on the ICxPS signal is detected, a capture event occurs, and the current value of the counter will be latched into the comparison capture register (R16_TIM1_CHCTLRx). When a capture event occurs, CCxIF (in R16_TIM1_INTFR) is set, and if interrupts or DMA are enabled, corresponding interrupts or DMA will also be generated. If CCxIF is already set when a capture event occurs, the CCxOF bit will be set. CCxIF can be cleared by software or by hardware by reading the compare capture register. CCxOF is cleared by software.

Take an example of channel 1 to illustrate the steps of using input capture mode, as follows:

- Configure the CCxS domain and select the source of the ICx signal. For example, set it to 10b and select TI1FP1 as the source of IC1 instead of using the default settings. The CCxS domain defaults to the comparison capture module as the output channel;
- 2) Configure the ICxF domain and set the digital filter for the TI signal. The digital filter will sample a certain frequency at a certain frequency, and then output a transition. This sampling frequency and number of times are determined by ICxF;
- 3) Configure the CCxP bit, set the polarity of TIxFPx. For example, keep the CC1P bit low and select rising edge transition;
- 4) Configure the ICxPS domain, set ICx signal to be the prescaler factors between ICxPS. Such as keep ICxPS as 00b, no prescaler;
- 5) Configure the CCxE bit allows capturing the value of the core counter (CNT) into the compare capture register. Set CC1E bit;
- 6) Configure the CCxIE and CCxDE bits as needed to decide whether to enable interrupts or DMA.

At this point, the comparison capture channel configuration has been completed.

When TI1 inputs a captured pulse, the value of the core counter (CNT) will be recorded in the compare capture register, and CC1IF will be set. When CC1IF has been set before, the CCIOF bit will also be set. If CC1IE is set, an interrupt will be generated; if CC1DE is set, a DMA request will be generated. An input capture event can be generated by software by writing to the event generation register (TIM1_SWEVGR).

9.3.2 Compare Output Mode

Compare output mode is one of the basic functions of a timer. The principle of the compare output mode is to output a specific change or waveform when the value of the core counter (CNT) is consistent with the value of the compare

capture register. The OCxM field (in R16_TIM1_CHCTLRx) and the CCxP bit (in R16_TIM1_CCER) determine whether the output is a definite high and low level or a level flip. When a comparison consistency event occurs, the CCxIF bit will also be set. If the CCxIE bit is set in advance, an interrupt will be generated; if the CCxDE bit is set in advance, a DMA request will be generated.

The steps to configure comparison output mode are as follows:

- 1) Configure the clock source and auto-reload value of the core counter (CNT);
- 2) Set the count value to be compared to the comparison capture register (R16_TIM1_CHxCVR);
- 3) If an interrupt needs to be generated, set the CCxIE bit;
- 4) Keep OCxPE at 0 to disable the preload register of the compare register;
- 5) Set the output mode, set the OCxM field and CCxP bit;
- 6) Enable the output and set the CCxE bit;
- 7) Set the CEN bit to start the timer.

9.3.3 Forced Output Mode

The output mode of the timer's compare capture channel can be forced to output a determined level by software without relying on the comparison of the shadow register of the compare capture register and the core counter. This is done by setting OCxM to 100b, which forces OCxREF to be set low, or by setting OCxM to 101b, which forces OCxREF to be set high.

It should be noted that when OCxM is forced to 100b or 101b, the comparison process of the internal core counter and the compare capture register is still in progress, the corresponding flag bit is still set, and interrupts and DMA requests are still generated.

9.3.4 PWM Input Mode

PWM input mode is used to measure the duty cycle and frequency of PWM. It is a special case of input capture mode. The operation is the same as input capture mode except for the following differences: PWM occupies two compare capture channels, and the input polarity of the two channels is set to opposite, one of the signals is set as the trigger input, and SMS is set in reset mode.

For example, to measure the period and frequency of the PWM wave input from TI1, you need to perform the following operations:

- 1) Set TI1 (TI1FP1) to the input of the IC1 signal. Set CC1S to 01b;
- 2) Set TI1FP1 to rising edge active. Hold CC1P at 0;
- 3) Set TI1 (TI1FP2) to the input of the IC2 signal. Set CC2S to 10b;
- 4) Select TI1FP2 to be falling edge active. Set CC2P to 1;
- 5) Select TI1FP1 for the source of the clock source. set TS to 101b;
- 6) Set SMS to reset mode, i.e. 100b;
- 7) Enable input capture. CC1E and CC2E are set;

In this way, the value of comparison capture register 1 is the period of PWM, and the value of comparison capture register 2 is its duty cycle.

Note: Since only T11FP1 and T12FP2 are connected to the slave mode controller, only TIM1_CH1/TIM1_CH2 can be used in the PWM input mode.

9.3.5 PWM Output Mode

PWM output mode is one of the basic functions of the timer. The most common method of PWM output mode is to use the reload value to determine the PWM frequency and the capture compare register to determine the duty cycle.

Set the OCxM field to 110b or 111b to use PWM mode 1 or mode 2, set the OCxPE bit to enable the preload register, and finally set the ARPE bit to enable automatic reloading of the preload register. Since the value of the preload register can be sent to the shadow register when an update event occurs, the UG bit needs to be set to initialize all registers before the core counter starts counting. In PWM mode, the core counter and compare capture register are constantly comparing, and the timer can output edge-aligned or center-aligned PWM signals according to the CMS bit.

• Edge aligned

When edge aligned is used, the core counter counts up or down. In the case of PWM mode 1, when the value of the core counter is greater than the compare capture register, OCxREF is high; when the value of the core counter is less than the compare capture register (such as the core counter grows to the value of R16_TIM1_ATRLR and returns to all 0), OCxREF is low.

• Center aligned

When using the center aligned mode, the core counter runs in an alternating up-counting and down-counting mode, and OCxREF performs rising and falling transitions when the values of the core counter and the compare capture register are consistent. However, the timing of setting the comparison flag is different in the three center aligned modes. When using center aligned mode, it is best to generate a software update flag (set the UG bit) before starting the core counter.

9.3.6 Complementary Outputs and Dead-time Insertion

The compare capture channel generally has two output pins, which can output two complementary signals (OCx and OCxN). OCx and OCxN can independently set the polarity through the CCxP and CCxNP bits, and independently set the output enable through CCxE and CCxNE. Dead-time and other controls are performed through MOE, OIS, OISN, OSSI, and OSSR bits. Enabling both the OCx and OCxN outputs will insert dead-time, with each channel having a 10-bit dead-time generator. If there is a brake circuit, the MOE bit must also be set. OCx and OCxN are generated by the association of OCxREF. If OCx and OCxN are both high and active, then OCx is the same as OCxREF, except that the rising edge of OCx is equivalent to OCxREF with a delay. OCxN is opposite to OCxREF. Its rising edge is relative to the falling edge of the reference signal. There will be a delay, and if the delay is greater than the effective output width, the corresponding pulse will not be generated.

Figure 9-4 shows the relationship between OCx, OCxN and OCxREF, and shows the dead-time.

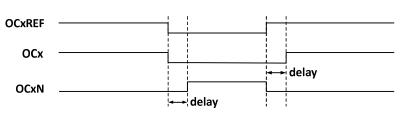

Figure 9-4 Complementary outputs and dead-time insertion

9.3.7 Brake Signal

When the brake signal is generated, the output enable signal and invalid level will be modified according to the MOE, OIS, OISN, OSSI and OSSR bits. But OCx and OCxN will not be at active levels at any time. The brake event source can come from the brake input pin.

After the system is reset, the braking function is disabled by default (MOE bit is low). Setting the BKE bit can enable the braking function. The polarity of the input braking signal can be set by setting BKP. The BKE and BKP signals can be written at the same time. There will be an HB clock delay before actual writing, so you need to wait

for an HB cycle to correctly read the written value.

When the selected level appears on the brake pin, the system will produce the following actions:

- 1) The MOE bit is cleared asynchronously, and the output is set to the inactive state, idle state, or reset state according to the setting of the SOOI bit;
- 2) After MOE is cleared, each output channel outputs the level determined by OISx;
- 3) When using complementary outputs: the outputs are put into an inactive state, depending on the polarity;
- 4) If BIE is set, an interrupt will be generated when BIF is set; if the BDE bit is set, a DMA request will be generated;
- 5) If AOE is set, the MOE bit is automatically set on the next update event UEV.

9.3.8 One-pulse Mode

One-pulse mode (OPM) can be used to allow the microcontroller to respond to a specific event by generating a pulse after a delay. The delay and pulse width are programmable. Setting the OPM bit can cause the core counter to stop when the next update event UEV is generated (the counter rolls over to 0).

As shown in Figure 9-5, it is necessary to detect a rising edge on the TI2 input pin. After delaying Tdelay, a positive pulse of length Tpulse is generated on OC1:

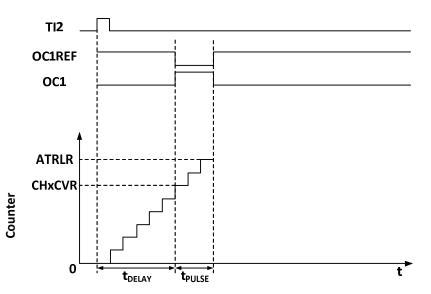

Figure 9-5 Generation of one pulse mode

- Set TI2 as trigger. Set CC2S field to 01b to map TI2FP2 to TI2; set CC2P bit to 0b to set TI2FP2 as rising edge detection; set TS field to 110b to set TI2FP2 as trigger source; and set SMS field to 110b for TI2FP2 to be used to start the counter;
- 2) Tdelay is determined by the value of the compare capture register, and Tpulse is determined by the value of the auto-reload value register and the value of the compare capture register.

9.3.9 Encoder Interface Mode

Encoder interface mode is a typical application of the timer. It can be used to access the bi-phase output of the encoder. The counting direction of the core counter is synchronized with the rotation axis direction of the encoder. Each time the encoder outputs a pulse, the core counter will increase by one or minus one. The steps to use the encoder are: set the SMS field to 001b (counting only on TI2 edges), 010b (counting only on TI1 edges) or 011b (counting on both TI1 and TI2 edges), and connect the encoder to compare capture channel 1, 2 input terminal, set a value for the reload value register, this value can be set larger. In encoder mode, the timer's internal compare

capture register, prescaler, repetition count register, etc. all work normally. The following table shows the relationship between counting direction and encoder signal.

| | The level of | TI1FP1 si | ignal edge | TI2FP2 | 2 signal |
|---------------------------|------------------|-----------|------------|----------|----------|
| Counting effective edges | relative signals | Rising | Falling | Rising | Falling |
| | Telative signais | edge | edge | edge | edge |
| | high | Downward | Upward | | |

| TI1 and TI2 | low | Upward | Downward | Downward | Upward |
| | 10 W | counting | counting | counting | counting |

Table 9-1 Relationship between counting direction and encoder signal of timer encoder mode

9.3.10 Timer Synchronization Mode

The timer can output clock pulses (TRGO) and can also receive input from other timers (ITRx). The sources of ITRx of different timers (TRGO of other timers) are different. The internal trigger connection of the timer is shown in Table 9-2.

Table 9-2 TIMx internal trigger connections

| Slave | ITR0(TS=000) | ITR1(TS=001) | ITR2(TS=010) | ITR3(TS=011) |
|-------|--------------|--------------|--------------|--------------|
| TIM2 | TIM1 | | | |

9.3.11 Debug Mode

When the system enters debug mode, the timer continues to run or stops according to the settings of the DBG module.

9.4 Register Description

Table 9-3 TIM1-related registers list

| Name | Access address | Description | Reset value |
|--------------------|----------------|------------------------------------|-------------|
| R16_TIM1_CTLR1 | 0x40012C00 | Control register 1 | 0x0000 |

| Bit | Name | Access | Description | Reset value |
|---------|----------|--------|---|-------------|
| 15 | CAPLVL | RW | In double-edge capture mode, the capture level indication is enabled. 0: Disable the indication function 1: Enable the indication function. Note: When enabled, CHxCVR[16] indicates the level corresponding to the capture value. | 0 |
| 14 | CAPOV | RW | Capture value mode configuration. 0: The capture value is the value of the actual counter 1: The CHxCVR value is 0xFFFF when a counter overflow is generated before capture. | 0 |
| [13:10] | Reserved | RO | Reserved | 0 |
| [9:8] | CKD[1:0] | RW | These 2 bits define the division ratio between the timer clock (CK_INT) frequency, the dead time and the sampling clock used by the dead time generator and the digital filter (ETR,TIx). 00: Tdts=Tck_int 01: Tdts = $2 \times Tck_int$ 10: Tdts = $4 \times Tck_int$ 11: Reserved. | 0 |
| 7 | ARPE | RW | Auto-reload preload enable bit. 1: Enable Auto-reload Value Register (ATRLR). 0: Disable Auto-reload Value Register (ATRLR). | 0 |
| [6:5] | CMS[1:0] | RW | Center aligned mode selection. 00: Edge-aligned mode. The counter counts up or down based on the direction bit (DIR). 01: Center-aligned mode 1. The counter counts up and down alternately. The output compare interrupt flag bit of the channel configured as output (CCxS=00 in the CHCTLRx register) is set only when the counter counts down. 10: Center-aligned mode 2. The counter counts up and down alternately. The output compare interrupt flag bit of the channel configured as output (CCxS=00 in the CHCTLRx register) is set only when the counter counts up. 11: Center-aligned mode 3. The counter counts up and down alternately. The output compare interrupt flag bit of the channel configured as output (CCxS=00 in the CHCTLRx register) is set only when the counter counts up. | 0 |

| | | | Note: When the counter is enabled (CEN=1), the transition from edge-aligned mode to center-aligned mode is not allowed. | |
|---|------|----|--|---|
| 4 | DIR | RW | Counting direction. 0: The counting mode of the counter is up counting; 1: The counting mode of the counter is down counting. <i>Note: This bit is not valid when the counter is</i> <i>configured in center-aligned mode or encoder interface</i> <i>mode.</i> | 0 |
| 3 | OPM | RW | One-pulse mode. 1: The counter stops (clear the CEN bit) when the next update event occurs. 0: The counter does not stop when the next update event occurs. | 0 |
| 2 | URS | RW | Update request source, by which the software selects the source of the UEV event. 1: If an update interrupt or DMA request is enabled, only an update interrupt or DMA request is generated if the counter overflows/underflows. 0: If an update interrupt or DMA request is enabled, an update interrupt or DMA request is generated by any of the following events. -Counter overflow/underflow -Setting the UG position -Updates generated by the slave mode controller | 0 |
| 1 | UDIS | RW | Disable updates, the software allows/disables the generation of UEV events by means of this bit. 1: UEV is disabled. no update event is generated and the registers (ARR, PSC, CCRx) keep their values. If the UG bit is set or a hardware reset is issued from the mode controller, the counters and prescaler are reinitialized. 0: UEV is allowed. update (UEV) events are generated by any of the following events: -Counter overflow/underflow -Setting the UG position - Updates generated by the slave mode controller Registers with caches are loaded with their preloaded values. | 0 |
| 0 | CEN | RW | Enables the counter. 1: Enable the counter. 0: Disable the counter. <i>Note: The external clock, gated mode and encoder</i> <i>mode will not work until the CEN bit is set in software.</i> <i>Trigger mode can automatically set the CEN bit in</i> <i>hardware.</i> | 0 |

9.4.2 Control Register 2 (TIM1_CTLR2)

| 8 | OIS1 | RW | • | 0 |
| 8 | 0151 | ĸw | Output idle state 1, see OIS3. | 0 |
| 7 | TIIS | RW | TI1 selection 1: TIMx_CH1, TIMx_CH2 and TIMx_CH3 pins connected to TI1 input (XOR combination). 0: TIMx_CH1 pin is connected directly to TI1 input. | 0 |
| [6:4] | MMS[2:0] | RW | Master mode selection: These 3 bits are used to select the synchronization information (TRGO) sent to the slave timer in master mode. Possible combinations are as follows: 000: Reset – The UG bit of the TIM1_EGR register is used as the trigger output (TRGO). If the reset is generated by the trigger input (the slave mode controller is in reset mode), there will be a delay between the signal on TRGO and the actual reset; 001: Enable – The counter enable signal CNT_EN is used as the trigger output (TRGO). Sometimes it is necessary to start multiple timers at the same time or control the slave timer to be enabled within a period of time. The counter enable signal is generated by the logical OR of the CEN control bit and the trigger input signal in gate mode. When the counter enable signal is controlled by the trigger input, there will be a delay on TRGO, unless the master/slave mode is selected (see the description of the MSM bit in the TIM1_SMCFGR register); 010: Update – The update event is selected as the trigger input (TRGO). For example, a master timer's clock can be used as a prescaler for a slave timer; 011: Compare pulse – When a capture occurs or a comparison is successful, when the CC11F flag is set (even if it is already high), the trigger output sends a positive pulse (TRGO); 100: The compare-OC1REF signal is used as a trigger output (TRGO); 101: The compare-OC2REF signal is used as a trigger output (TRGO); 101: The compare-OC3REF signal is used as a trigger output (TRGO); 111: Reserved. | 0 |
| 3 | CCDS | RW | Capture compare DMA selection 1: Send a DMA request for CHxCVR when an update event occurs. 0: Generate a DMA request for CHxCVR when CHxCVR occurs. | 0 |

| 2 | CCUS | RW | Compare capture control update selection bits. 1: If CCPC is set, they can be updated by setting the COM bit or a rising edge on TRGI. 0: If the CCPC is set, they can only be updated by setting the COM bit. Note: This bit only works for channels with complementary outputs. | 0 |
|---|----------|----|--|---|
| 1 | Reserved | RO | Reserved | 0 |
| 0 | CCPC | RW | Compare capture preload control bits. 1: The CCxE, CCxNE and OCxM bits are preloaded and when this bit is set they are only updated when the COM bit is set. 0: CCxE, CCxNE and OCxM bits are not preloaded. Note: This bit only works for channels with complementary outputs. | 0 |

9.4.3 Slave Mode Control Register (TIM1_SMCFGR)

This bit is set by hardware when the counter value matches the comparison value, except in centrosymmetric mode. This bit is cleared by software. 1: The value of the core counter matches the value of compare capture register 1; 0: No match occurs. If compare capture channel 1 is configured as input mode. This bit is set by hardware when a capture event occurs, and it is cleared by software or by reading the compare capture register. 1: The counter value has been captured compare capture register 1. | 0 | | | | |
| 0 | UIF | RW0 | 0: No input capture is generated. Update interrupt flag bit, this bit is set by hardware when an update event is generated and cleared by software. 1: Update interrupt generation. 0: No update event is generated. The following scenarios generate update events. If UDIS = 0, when the repeat counter value overflows or | 0 | | | | |

| | underflows. If URS = 0, UDIS = 0, when the UG bit is set, or when the counter core counter is reinitialized by software. If URS = 0, UDIS = 0, when the counter CNT is | |
|--|---|--|
| | reinitialized by a trigger event. | |

9.4.6 Event Generation Register (TIM1_SWEVGR)

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------|----|----|----|----|----|----|----|------|----------|------|------|------|----|---|---|
| Reserved | | | | | | BG | TG | COMG | Reserved | CC3G | CC2G | CC1G | UG | | |

| Bit | Name | Access | Description | Reset value |
|--------|----------|--------|--|-------------|
| [15:8] | Reserved | RO | Reserved | 0 |
| 7 | BG | WO | The brake event generation bit, which is set and cleared by software, is used to generate a brake event. 1: Generate a brake event. At this point, MOE=0, BIF=1, if the corresponding interrupt and DMA are enabled, the corresponding interrupt and DMA are generated. 0: No action. | 0 |
| 6 | TG | WO | The trigger event generation bit, which is set by software and cleared by hardware, is used to generate a trigger event. 1: Generate a trigger event, TIF is set, and the corresponding interrupts and DMAs are generated if enabled. 0: No action. | 0 |
| 5 | COMG | WO | Compare capture control update generation bit. Generates a compare capture control update event. This bit is set by software and automatically cleared by hardware. 1: When CCPC = 1, allow updating of CCxE, CCxNE, OCxM bits. 0: No action. Note: This bit is only valid for channels with complementary outputs (channels 1, 2, 3). | 0 |
| 4 | Reserved | RO | Reserved | 0 |
| 3 | CC3G | WO | Compare capture event generation bit 3. generates compare capture event 3. | 0 |
| 2 | CC2G | WO | Compare capture event generation bit 2. generates compare capture event 2. | 0 |
| 1 | CC1G | WO | Compare capture event generation bit 1. generates compare capture event 1. This bit is set by software and cleared by hardware. It is used to generate a compare capture event. 1: Generate a compare capture event on compare capture channel 1. If compare capture channel 1 is configured as output. Set the CC1IF bit. Generate the corresponding interrupts and DMAs if they are enabled. If compare capture channel 1 is configured as input. The current core counter value is captured to compare capture register 1; set the CC1IF bit to generate the corresponding interrupts and DMAs if they are enabled; | 0 |

| | | | if CC1IF is already set, set the CC1OF bit. 0: No action. | |
|---|----|----|--|---|
| 0 | UG | WO | Update event generation bit to generate an update event. This bit is set by software and is automatically cleared by hardware. 1: Initialize the counter and generate an update event. 0: No action. Note: The prescaler counter is also cleared to zero, but the prescaler factor remains unchanged. The core counter is cleared if in centrosymmetric mode or incremental counting mode; if in decremental counting mode, the core counter takes the value of the reload value register. | 0 |

9.4.7 Compare/Capture Control Register 1 (TIM1_CHCTLR1)

Offset address: 0x18

The channel can be used in input (capture mode) or output (compare mode), and the direction of the channel is defined by the corresponding CCxS bit. The other bits of this register have different roles in input and output modes. OCxx describes the function of the channel in output mode and ICxx describes the function of the channel in input mode.

Compare mode (pin direction is output).

| Bit | Name | Access | Description | Reset value |
|---------|-----------|--------|---|-------------|
| 15 | OC2CE | RW | Compare capture channel 2 clear enable bit. 1: Clear OC2REF bit zero once ETRF input is detected high; 0: OC2REF is not affected by ETRF input. | 0 |
| [14:12] | OC2M[2:0] | RW | Compare Capture Channel 2 mode setting field. The 3 bits define the action of the output reference signal OC2REF, which determines the values of OC2, OC2N. OC2REF is active high, while the active levels of OC2 and OC2N depend on the CC2P, CC2NP bits. 000: Freeze. The comparison value between the value of the capture register and the core counter has no effect on OC2REF; 001: Forced to valid level. When the core counter has the same value as compare capture register 2, force OC2REF to be high; 010: Forced to invalid level. When the value of the core counter is the same as compare capture register 2, force OC2REF low; 011: Flip. When the value of the core counter and compare capture register 2 are the same, flip the level of OC2REF; 100: Forced to invalid level. Force OC2REF low; 101: Forced to valid level. Force OC2REF low; 101: Forced to valid level. Force OC2REF high; 110: PWM mode 1: When counting up, once the core counter is less than the value of the comparison capture register, channel 2 is an effective level, otherwise it is an invalid level; When counting down, once the core | 0 |

| | r | - | | |
|-------|-----------|----|--|---|
| | | | counter is greater than the value of the comparison capture register, channel 2 is at an invalid level (OC2REF=0), otherwise it is at an effective level (Oc2Ref = 1); 111: PWM mode 2: When counting up, once the core counter is less than the value of the comparison capture register, channel 2 is at an invalid level, otherwise it is at an effective level; When counting down, once the core counter is greater than the value of the comparison capture register, Channel 2 is active (OC2REF=1), otherwise it is inactive (OC2REF=0). <i>Note: Once the LOCK level is set to 3 and CC2S=00b,</i> <i>this bit cannot be modified. In PWM mode 1 or PWM</i> <i>mode 2, the OC2REF level changes only when the</i> <i>comparison result changes or when switching from</i> | |
| 11 | OC2PE | RW | freeze mode to PWM mode in output compare mode.Compare capture register 2 preload enable bit.1: Enable the preload function of compare captureregister 2. Read and write operations only operate onthe preload register. The preload value of comparecapture register 2 is loaded into the current shadowregister when the update event arrives;0: Disable the preload function of compare captureregister 2, you can write to compare capture register 2at any time, and the newly written value will take effectimmediately.Note: Once the LOCK level is set to 3 and CC2S=00,this bit cannot be modified; only in single pulse mode(OPM=1), the PWM mode can be used withoutconfirming the preload register, otherwise its action isuncertain. | 0 |
| 10 | OC2FE | RW | <i>uncertain.</i> Compare capture channel 2 fast enable bit, which is used to speed up the response of the compare capture channel output to trigger input events. 1: The valid edge input to the flip-flop acts as if a compare match occurred. Therefore, OC is set to the comparison level regardless of the comparison result. The delay between the valid edge of the sampling flip-flop and the output of compare capture channel 2 is shortened to 3 clock cycles; 0: Based on the value of the counter and compare capture register 1, compare capture channel 2 operates normally, even if the flip-flop is open. The minimum delay to activate the compare capture channel 2 output is 5 clock cycles when the input of the flipflop has a valid edge. OC2FE only works when the channel is configured to PWM1 or PWM2 mode. | 0 |
| [9:8] | CC2S[1:0] | RW | Compare capture channel 2 input selection fields. 00: Compare capture channel 2 is configured as an output. 01: Compare capture channel 2 is configured as an input and IC2 is mapped on TI2. 10: Compare capture channel 2 is configured as an input and IC2 is mapped on TI1. 11: Compare Capture Channel 2 is configured as an input and IC2 is mapped on TI1. 11: Compare Capture Channel 2 is configured as an input and IC2 is mapped on TRC. This mode works only when the internal trigger input is selected (by the | 0 |

| | | | TS bit). | |
|-------|-----------|----|---|---|
| | | | Note: Compare Capture Channel 2 is writable only | |
| | | | when the channel is off (when CC2E is zero). | |

Chapter 10 General-Purpose Timer (GPTM)

The general-purpose timer module contains a 16-bit auto-reloadable timer (TIM2), for measuring pulse width or generating pulses of a specific frequency, PWM waves, etc. It can be used in automation control, power supply, etc.

10.1 Main Features

The main features of the general-purpose timer include:

- 16-bit auto-reload counter, supports incremental counting mode
- 16-bit prescaler with dynamically adjustable crossover factor from 1 to 65536
- Support 2 independent comparison capture channels
- Each compare capture channel supports multiple operating modes, such as: input capture, output compare, PWM generation, and single pulse output
- Support external signal control timer
- Support cascading and synchronization between timers
- Support simple dead-time control

10.2 Principle and Structure

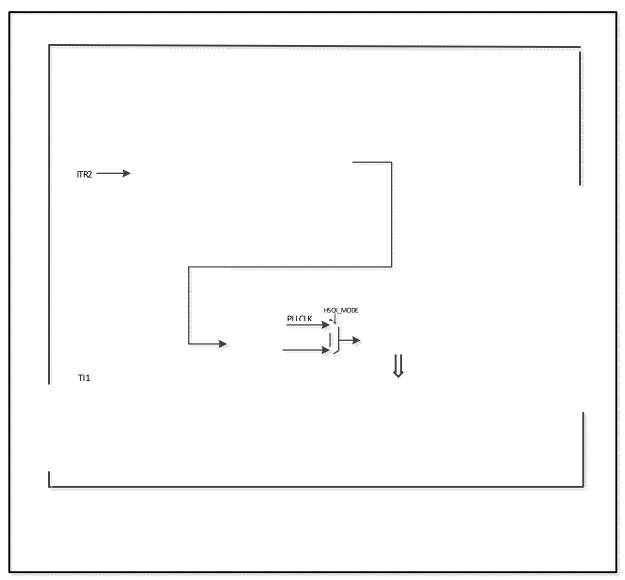

Figure 10-1 Block diagram of the structure of the general-purpose timer

10.2.1 Overview

As shown in Figure 10-1, the structure of the general timer can be roughly divided into three parts, namely the input clock part, the core counter part and the compare capture channel part.

The clock of the general timer can come from the HB bus clock (CK_INT), from other timers with clock output function (ITRx), or from the input end of the compare capture channel (TIM2_CHx). These input clock signals become the CK_PSC clock after various set filtering and frequency division operations, and are output to the core counter part.

The core of the general-purpose timer is a 16-bit counter (CNT). After CK_PSC is divided by the prescaler (PSC), it becomes CK_CNT and is finally lost to CNT. CNT supports up-counting mode and has an automatic reload value register (ATRLR) that reloads and initializes CNT after each counting cycle. value.

The general-purpose timer has two sets of compare capture channels. Each set of compare capture channels can input pulses from a dedicated pin or output a waveform to the pin. That is, the compare capture channel supports

input and output modes. The input of each channel of the compare capture register supports filtering, frequency division, edge detection and other operations, supports mutual triggering between channels, and can also provide a clock for the core counter CNT. Each compare capture channel has a set of compare capture registers (CHxCVR) that support comparison with the main counter (CNT) and output pulses.

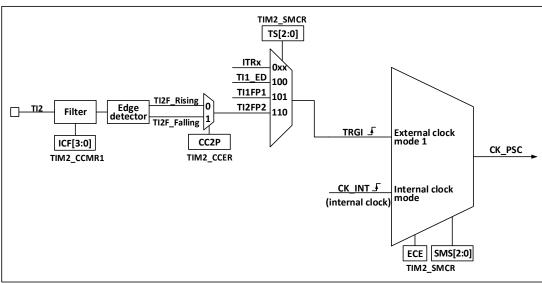

10.2.2 Differences between General-Purpose Timer and Advanced-Control Timer

Compared to advanced-control timers, general-purpose timers lack the following features.

- 1) General-purpose timers lack a repeat count register for counting the count cycles of the core counter.
- 2) General-purpose timers do not have a brake signal mechanism.
- 3) General purpose timers do not have encoder mode.
- 4) General purpose timers do not support the use of DMA in multiple modes.
- 5) General timer 16-bit auto-reload counter does not support down-counting mode and up-down counting mode.
- 6) General-purpose timers do not support the external clock pin (ETR) input clock.

10.2.3 Clock Input

This section discusses the origin of CK_PSC. Here is the clock source part of the overall structure block diagram of the general-purpose timer.

The optional input clocks can be divided into 4 categories:

- 1) Internal HB clock input route: CK_INT.
- 2) Route from the compare capture channel pin (TIMx_CHx): TIMx_CHx \rightarrow TIx \rightarrow TIxFPx;
- 3) Input from other internal timers: ITRx.

The actual operation can be divided into 3 categories by determining the choice of input pulse for the SMS of the CK_PSC source.

- 1) Selection of the internal clock source (CK_INT).
- 2) External clock source mode 1.

All 2 clock source sources mentioned above can be selected by these 2 operations.

10.2.3.1 Internal Clock Source (CK_INT)

If the general-purpose timer is started when the SMS field is held at 000b, then it is the internal clock source (CK_INT) that is selected as the clock. At this point CK_INT is CK_PSC.

10.2.3.2 External Clock Source Mode 1

When the SMS domain is set to 111b, external clock source mode 1 is enabled. When external clock source 1 is enabled, TRGI is selected as the source for CK_PSC. it is worth noting that the user also needs to select the source for TRGI by configuring the TS domain. The TS domain can select the following types of pulses as clock sources.

- 1) Internal trigger (ITRx, x is 0,1,2,3).
- 2) Compare/capture the signal of channel 1 after passing through the edge detector (TI1F_ED);
- 3) Compare/capture channel signal TI1FP1, TI2FP2

10.2.3 Counters and Peripherals

CK_PSC is input to the prescaler (PSC) for dividing the frequency, the PSC is 16-bit and the actual dividing factor is equal to the value of R16_TIM2_PSC + 1. CK_PSC becomes CK_INT after passing through the PSC. Changing the value of R16_TIM1_PSC will not take effect in real time, but will be updated to the PSC after an update event which includes the UG bit clear and reset. Update events include UG bit clear and reset.

10.2.4 Compare/Capture Channels

The compare capture channel is the core of the timer to achieve complex functions. Its core is the comparison capture register, supplemented by the digital filtering of the peripheral input part, frequency division and interchannel multiplexing, and the comparator and output control of the output part. The structural block diagram of the compare capture channel is shown in Figure 10-3.

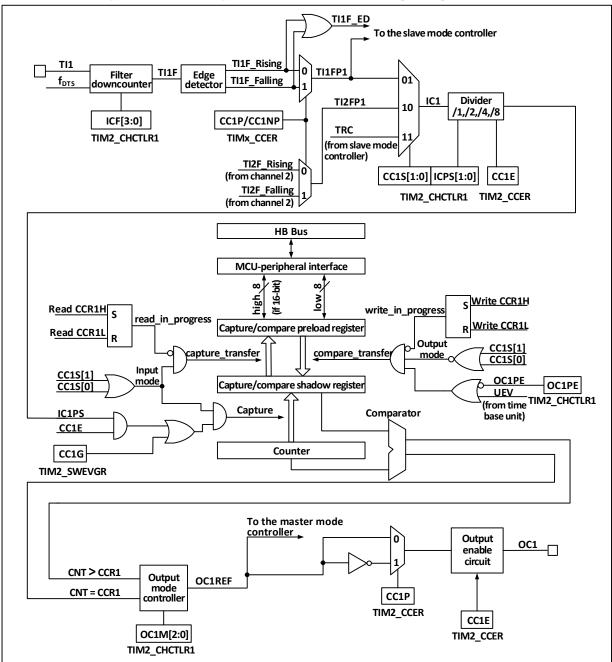

Figure 10-3 Block diagram of the structure of the compare capture channel

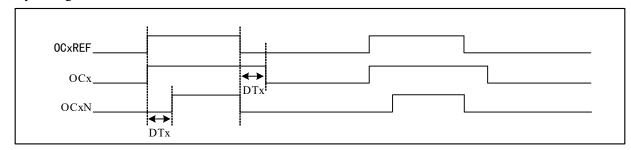

The signal is input from the channel x pin and optionally made as TIx (the source of TI1 can be more than CH1, see block diagram 10-1 of the timer), TI1 is passed through the filter (ICF[3:0]) to generate TI1F, and then divided into TI1F_Rising and TI1F_Falling through the edge detector, these two signals are selected (CC1P) to generate TI1FP1, TI1FP1 and TI2FP1 from channel 2 are sent together to CC1S to select to become IC1, which is sent to the compare capture register after ICPS dividing.

The compare capture register consists of a preload register and a shadow register, and the read/write process operates only on the preload register. In capture mode, the capture occurs on the shadow register and is then copied to the preload register; in compare mode, the contents of the preload register are copied to the shadow register, and then the contents of the shadow register are compared to the core counter (CNT).

10.2.5 Complementary Outputs and Dead-time

2 channels generally have two output pins, which can output two complementary signals with dead zones (OCx and

OCxN). The polarity is independently controlled through the COxP and COxNP bits, and the dead zone time can be set by setting the DTx bit.

10.3 Function and Implementation

The realization of the complex functions of the general timer is achieved by operating the timer's comparE capture channel, clock input circuit, counter and peripheral components. The clock input to the timer can come from multiple clock sources including the input to the compare capture channel. The operation of compare capture register channel and clock source selection directly determines its function. The compare capture channel is bidirectional and can work in input and output modes.

10.3.1 Input Capture Mode

Input capture mode is one of the basic functions of the timer. The principle of the input capture mode is that when a certain edge on the ICxPS signal is detected, a capture event is generated, and the current value of the counter will be latched into the comparison capture register (R16_TIM2_CHCTLRx). When a capture event occurs, CCxIF (in R16_TIM2_INTFR) is set, and if interrupts are enabled, corresponding interrupts will be generated. If CCxIF is already set when a capture event occurs, the CCxOF bit will be set. CCxIF can be cleared by software or by hardware by reading the compare capture register. CCxOF is cleared by software.

Take an example of channel 1 to illustrate the steps of using input capture mode, as follows:

- Configure the CCxS domain and select the source of the ICx signal. For example, if it is set to 10b and TI1FP1 is selected as the source of IC1, the default settings cannot be used. The default setting of the CCxS domain is to use the comparison capture module as the output channel;
- 2) Configure the ICxF domain and set the digital filter for the TI signal. The digital filter will sample a certain frequency at a certain frequency, and then output a transition. This sampling frequency and number of times are determined by ICxF;
- 3) Configure the CCxP bit to set the polarity of TIxFPx. For example, keep the CC1P bit low and select rising edge transition;
- 4) Configure the ICxPS field to set the crossover coefficient between which the ICx signal becomes ICxPS. For example, keep ICxPS as 00b without crossover;
- 5) Configuring the CCxE bit allows capturing the value of the core counter (CNT) into the compare capture register. Set CC1E bit;
- 6) Configure the CCxIE and CCxDE bits as needed to decide whether to enable interrupts.

At this point, the compare capture channel configuration has been completed.

When TI1 inputs a captured pulse, the value of the core counter (CNT) will be recorded in the compare capture register, and CC1IF will be set. When CC1IF has been set before, the CCIOF bit will also be set. If CC1IE is bit, then an interrupt will be generated. An input capture event can be generated by software by writing to the event generation register (R16_TIM2_SWEVGR).

10.3.2 Compare Output Mode

Compare output mode is one of the basic functions of a timer. The principle of the compare output mode is to output a specific change or waveform when the value of the core counter (CNT) is consistent with the value of the compare capture register. The OCxM field (in R16_TIM2_CHCTLRx) and the CCxP bit (in R16_TIM2_CCER) determine whether the output is a definite high and low level or a level flip. When a comparison consistency event occurs, the CCxIF bit will also be set. If the CCxIE bit is set in advance, an interrupt will be generated.

The steps to configure compare output mode are as follows:

- 1) Configure the clock source and auto-reload value of the core counter (CNT);
- 2) Set the count value to be compared into the compare capture register (R16_TIM2_CHxCVR);
- 3) If an interrupt needs to be generated, set the CCxIE bit;
- 4) Keep OCxPE at 0 to disable the preload register of the compare capture register;
- 5) Set the output mode, set the OCxM field and CCxP bit;
- 6) Enable the output and set the CCxE bit;
- 7) Set the CEN bit to start the timer.

10.3.3 Forced Output Mode

The output mode of the timer's compare capture channel can be forced to output a determined level by software without relying on the comparison of the shadow register of the compare capture register and the core counter. This is done by setting OCxM to 100b, which forces OCxREF to be set low, or by setting OCxM to 101b, which forces OCxREF to be set high.

It should be noted that when OCxM is forced to 100b or 101b, the comparison process between the internal main counter and the compare capture register is still in progress, the corresponding flag bit is still set, and interrupts are still generated.

10.3.4 PWM Input Mode

PWM input mode is used to measure the duty cycle and frequency of PWM. It is a special case of input capture mode. The operation is the same as input capture mode except for the following differences: PWM occupies two compare capture channels, and the input polarity of the two channels is set to opposite, one of the signals is set as the trigger input, and SMS is set in reset mode.

For example, to measure the period and frequency of the PWM wave input from TI1, you need to perform the following operations:

- 1) Set TI1 (TI1FP1) to be the input of IC1 signal. Set CC1S to 01b.
- 2) Set TI1FP1 to rising edge active. Holding CC1P at 0.
- 3) Set TI1 (TI1FP2) as the input of IC2 signal. Set CC2S to 10b.
- 4) Select TI1FP2 to set to falling edge active. Set CC2P to 1.
- 5) Select TI1FP1 as the source of the clock source. set TS to 101b.
- 6) Set the SMS to reset mode, i.e. 100b.
- 7) Enables input capture. CC1E and CC2E are set.

Note: Since only TI1FP1 and TI2FP2 are connected to the slave mode controller, only TIM2_CH1/TIM2_CH2 can be used in the PWM input mode.

10.3.5 PWM Output Mode

PWM output mode is one of the basic functions of the timer. The most common method of PWM output mode is to use the reload value to determine the PWM frequency and the capture compare register to determine the duty cycle.

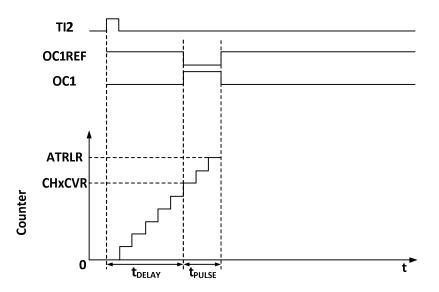

Set the OCxM field to 110b or 111b to use PWM mode 1 or mode 2, set the OCxPE bit to enable the preload register, and finally set the ARPE bit to enable automatic reloading of the preload register. The value of the preload register can be sent to the shadow register when an update event occurs, so before the core counter starts counting, the UG bit needs to be set to initialize all registers.

• Edge aligned

When using edge alignment, the core counter counts up. In the case of PWM mode 1, when the value of the core counter is greater than the compare capture register, OCxREF rises to high; when the value of the core counter is less than the compare capture register (for example, the core counter increases to R16_TIM2_ATRLR value returns to all 0), OCxREF falls low.

10.3.6 One-pulse Mode

Single pulse mode generates a pulse in response to a specific event followed by a delay with programmable delay and pulse width. Setting the OPM bit can cause the core counter to stop when the next update event UEV is generated (the counter rolls over to 0).

As shown in Figure 10-4, a rising edge needs to be detected on the TI2 input pin. After a delay of Tdelay, a positive pulse of length Tpulse is generated on OC1:

- Set TI2 to trigger. Setting the CC2S field to 01b to map TI2FP2 to TI2; setting the CC2P bit to 0b to set TI2FP2 as rising edge detection; setting the TS field to 110b to set TI2FP2 as trigger source; setting the SMS field to 110b to set TI2FP2 to be used to start the counter.
- 2) Tdelay is defined by the Compare Capture Register, Tpulse is determined by the value of the Auto Reload Value Register and the Compare Capture Register.

10.3.7 Synchronization of Timers

The timer can output clock pulses (TRGO) and can also receive input from other timers (ITRx). The sources of ITRx of different timers (TRGO of other timers) are different. The internal trigger connection of the timer is shown in Table 10-2.

| | | 66 | | |
|-------------|--------------|--------------|--------------|--------------|
| Slave timer | ITR0(TS=000) | ITR1(TS=001) | ITR2(TS=010) | ITR3(TS=011) |
| TIM2 | TIM1 | | | |

Table 10-1 GTPM internal trigger connections

10.3.8 Debug mode

When the system enters the debug mode, the timer can be controlled to continue running or stop according to the setting of DBG module.

10.4 Register Description

Table 10-2 TIM2-related registers list

| Name | Access address | Description | Reset value | | | | | | | | | |

| 10 | CC2OF | RW0 | Compare capture channel 2 over-capture flag. | 0 |
| 9 | CC10F | RW0 | Compare capture channel 1 over-capture flag bit is only used when the compare capture channel is configured for input capture mode. This flag is set by hardware and a software write of 0 clears this bit. 1: The state of CC1IF has been set when the counter value is captured to the capture compare register; 0: No over-capture generated. | 0 |
| [8:7] | Reserved | RO | Reserved | 0 |
| 6 | TIF | RW0 | The trigger interrupt flag bit, which is set by hardware to this position when a trigger event occurs and cleared by software. Trigger events include the detection of a valid edge at the TRGI input when from a mode other than gated, or any edge in gated mode. 1: Trigger event generated; 0: No trigger event generated. | 0 |
| [5:3] | Reserved | RO | Reserved | 0 |
| 2 | CC2IF | RW0 | Compare capture channel 2 interrupt flag | 0 |
| 1 | CC1IF | RW0 | Compare capture channel 1 interrupt flag If the compare capture channel is configured in output mode, this bit is set by hardware when the counter value matches the compare value, except in center-symmetric mode. This bit is cleared by software. 1: The value of the core counter matches the value of the compare capture register 1; 0: No match occurs. If compare capture channel 1 is configured in input mode, this bit is set by hardware when a capture event occurs, and it is cleared by software or by reading the compare capture register. 1: The counter value has been captured by comparing the capture register 1; 0: No input capture is generated. | |
| 0 | UIF | RW0 | Update interrupt flag bit. When an update event occurs, this bit is set by hardware and cleared by software. | 0 |

| 1: Update interrupt occurs; 0: No update event occurs. The following situations will generate update events: If UDIS=0, when the repetition counter value overflows or underflows; If URS=0, UDIS=0, when the UG bit is set, or when the counter core counter is reinitialized through software; If URS=0, UDIS=0, when the counter CNT is | |
|--|--|
| reinitialized by a trigger event; | |

10.4.5 Event Generation Register (TIM2_SWEVGR)

| Bit | Name | Access | Description | Reset value |
|--------|----------|--------|--|-------------|
| [15:7] | Reserved | RO | Reserved | 0 |
| 6 | TG | WO | Trigger event generation bit, this bit is set by software and cleared by hardware to generate a trigger event. 1: A trigger event is generated, TIF is set, and if the corresponding interrupt is enabled, the corresponding interrupt is generated; 0: No action. | 0 |
| [5:3] | Reserved | RO | Reserved | 0 |
| 2 | CC2G | WO | Compare capture event generates bit 2. Generates compare capture event 2. | 0 |
| 1 | CC1G | WO | Compare capture event generates bit 1, generates compare capture event 1. This bit is set by software and cleared by hardware. Used to generate a compare capture event. 1: Generate a compare capture event on compare capture channel 1: If compare capture channel 1 is configured as output: set the CC1IF bit. If the corresponding interrupt is enabled, the corresponding interrupt is generated; If the comparison capture channel 1 is configured as input: the value of the current core counter is captured to the comparison capture register 1; the CC1IF bit is set, and if the corresponding interrupt is generated. of interruption. If CC1IF is already set, set CC1OF bit. 0: No action. | 0 |
| 0 | UG | | The update event generation bit generates an update event. This bit is set by software and automatically cleared by hardware. 1: Initialize the counter and generate an update event; 0: No action. Note: The prescaler counter is also cleared, but the prescaler coefficient remains unchanged. If it is in the center symmetry mode or the up-counting mode, the core counter is cleared; if it is in the down-counting mode, the core counter takes the value of the reload value register. | 0 |

10.4.6 Compare/Capture Control Register 1 (TIM2_CHCTLR1)

Offset address: 0x18

Channels can be used as input (capture mode) or output (compare mode), and the direction of the channel is defined by the corresponding CCxS bit. The functions of other bits in this register are different in input and output modes. OCxx describes the function of the channel in output mode, and ICxx describes the function of the channel in input mode.

| Bit | Name | Access | Description | Reset value |
|---------|-----------|--------|--|-------------|
| 15 | Reserved | RO | Reserved | 0 |
| [14:12] | OC2M[2:0] | RW | Compare capture channel 2 mode setting fields. The 3 bits define the action of the output reference signal OC2REF, which determines the values of OC2, OC2N. OC2REF is active high, while the active levels of OC2 and OC2N depend on the CC2P, CC2NP bits. 000: Freeze. Comparison of the value of the capture register with the value of the comparison between the core counters does not work for OC2REF. 001: Force to set to valid level. Forcing OC2REF high when the core counter has the same value as the comparison capture register 2. 010: Force to set to invalid level. Forcing OC2REF low when the value of the core counter is the same as the comparison capture register 2. 011: Flip. Flips the level of OC2REF when the core counter is the same as the value of compare capture register 2. 100: Forced to invalid level. Forces OC1REF to low. 101: Force to valid level. Force OC1REF to high. 110: PWM mode 1: When counting up, once the core counter is less than the value of the comparison capture register, channel 2 is an effective level, otherwise it is an invalid level; 111: PWM mode 2: When counting up, once the core counter is less than the value of the comparison capture register, channel 2 is at an invalid level, otherwise it is at an effective level. <i>Note: Once the LOCK level is set to 3 and CC2S=00b,</i> <i>this bit cannot be modified. In PWM mode 1 or PWM</i> <i>mode 2, the OC2REF level changes only when the</i> <i>comparison result changes or when switching from</i> <i>freeze mode to PWM mode in output compare mode.</i> | 0 |
| 11 | OC2PE | RW | Compare capture register 2 preload enable bit. 1: Enable the preload function of compare capture register 2. Read and write operations only operate on the preload register. The preload value of compare capture register 2 is loaded into the current shadow register when the update event arrives; 0: Disable the preload function of compare capture | 0 |

| | | | register 2. Compare capture register 2 can be written to at any time, and the newly written value will take effect immediately. Note: Once the LOCK level is set to 3 and CC2S=00, this bit cannot be modified. PWM mode can be used only in single pulse mode (OPM=1) without confirming the preload register, otherwise its action is uncertain. | |
|-------|-----------|----|---|---|
| 10 | OC2FE | RW | Compare capture channel 2 fast enable bit, which is used to speed up the response of the compare capture channel output to trigger input events. 1: The active edge of the input to the flipflop acts as if a comparison match has occurred. Therefore, the OC is set to the comparison level independent of the comparison result. The delay between the valid edge of the sample trigger and the output of the compare capture channel 2 is reduced to 3 clock cycles. 0: Based on the value of the counter and compare capture register 1, compare capture channel 2 operates normally, even if the flip-flop is open. The minimum delay to activate the compare capture channel 2 output is 5 clock cycles when the input of the flipflop has a valid edge. OC2FE only works when the channel is configured to PWM1 or PWM2 mode. | 0 |
| [9:8] | CC2S[1:0] | RW | Compare capture channel 2 input selection fields. 00: comparison capture channel 2 is configured as an output. 01: comparison capture channel 2 is configured as an input and IC2 is mapped on TI2. 10: comparison capture channel 2 is configured as an input and IC2 is mapped onTI1. 11: Compare Capture Channel 2 is configured as an input and IC2 is mapped on TRC. This mode works only when the internal trigger input is selected (by the TS bit). Note: Compare capture channel 2 is writable only when the channel is off (when CC2E is zero). | 0 |
| 7 | Reserved | RO | Reserved | 0 |
| [6:4] | OC1M[2:0] | RW | Compare capture channel 1 mode setting field. | 0 |

Chapter 11 Universal Synchronous Asynchronous Receiver

Transmitter (USART)

The module contains one Universal Synchronous Asynchronous Transceiver (USART).

11.1 Main Features

- Full-duplex or half-duplex synchronous or asynchronous communication
- NRZ data format
- Fractional baud rate generator, up to 3Mbps
- Programmable data length
- Configurable stop bits
- Support LIN, IrDA encoders
- Support DMA
- Multiple interrupt sources

11.2 Overview

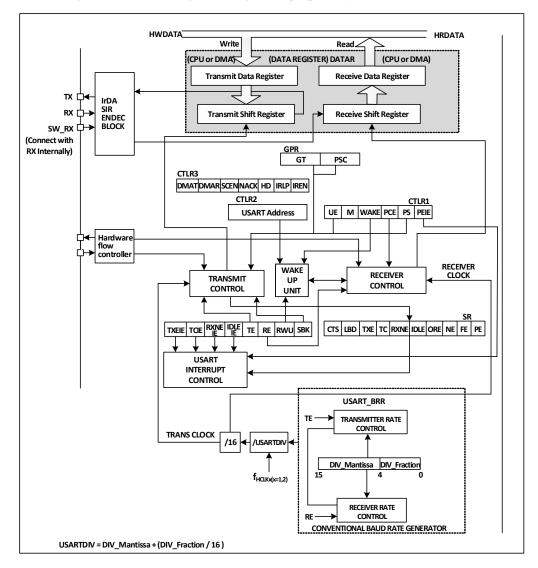

Figure 11-1 Block diagram of a general-purpose asynchronous transceiver

When TE (transmit enable bit) is set, the data in the transmit shift register is output on the TX pin and the clock is output on the CK pin. When transmitting, the first bit shifted out is the least significant bit and each data frame starts with a low start bit, then the transmitter sends an 8- or 9-bit data word depending on the setting on the M (word length) bit, and finally a configurable number of stop bits. If equipped with a parity check bit, the last bit of the data word is the check bit. After the TE is set an idle frame is sent, which is 10 or 11 bits high and contains the stop bit. The disconnect frame is 10 or 11 bits low followed by the stop bit.

11.3 Baud Rate Generator

The baud rate of the transceiver = HCLK/(16*USARTDIV), HCLK is the clock of HB. The value of USARTDIV is determined by the two fields DIV_M and DIV_F in USART_BRR, which is calculated by the formula. The formula is as follows.

$USARTDIV = DIV_M + (DIV_F/16)$

It should be noted that the baud rate generated by the baud rate generator may not be just what the user needs, which

may be biased. In addition to taking the value as close as possible, a way to reduce the deviation can also be to increase the HB clock. For example, if you set the baud rate to 115200bps, the value of USARTDIV is set to 39.0625, which will give you a baud rate of exactly 115200bps at the highest frequency, but if you need a baud rate of 921600bps, the calculated USARTDIV is 4.88, but the closest value filled in USART_BRR is actually only 4.875, the actual baud rate is 923076bps, which is 0.16% error.

When the serial port waveform sent by the sender is transmitted to the receiver, there is a certain error in the baud rate of the receiver and the sender. The error mainly comes from three aspects: the actual baud rate of the receiver and the sender is inconsistent; there is an error in the clock of the receiver and the sender; and the change of the waveform in the line. The receiver of the peripheral module has a certain receiving tolerance. When the sum of the total deviations generated by the above three aspects is less than the tolerance limit of the module, this total deviation does not affect the transmission and reception. The tolerance limit of the module is affected by whether the fractional baud rate and M bits (data field word length) are used. The use of fractional baud rate and the use of 9-bit data field length will reduce the tolerance limit, but not less than 3%.

11.4 1-Wire Half-Duplex Mode

Half-duplex mode supports the use of a single pin (only the TX pin) for receiving and transmitting. The TX pin and RX pin are connected internally in the chip.

The way to turn on the half-duplex mode is to set the HDSEL bit in the control register 3 (R32_USARTx_CTLR3), but at the same time, you need to turn off the LIN mode and the infrared mode, that is, ensure that the IREN bit is in the reset state, which is in the control register 3 (R32_USART_CTLR3).

After setting to half-duplex mode, you need to set the TX IO port to multiplexed output high mode. With TE set, as long as data is written to the data register, it will be sent. In particular, it is important to note that in half-duplex mode, bus conflicts may occur when multiple devices use a single bus to send and receive, which requires users to use software to avoid it.

11.5 IrDA

The USART module supports control of IrDA infrared transceivers for physical layer communication. The LINEN, STOP, CLKEN, SCEN and HDSEL bits must be cleared to use IrDA. NRZ (non-return to zero) coding is used between the USART module and the SIR physical layer (infrared transceiver) and is supported up to 115200 bps rates.

IrDA is a half-duplex protocol, if UASRT is sending data to SIR physical layer, then IrDA decoder will ignore the newly sent IR signal, if USART is receiving data from SIR, then SIR will not accept the signal from USART. the level logic of USART to SIR and SIR to USART is different. In SIR receive logic, the high level is 1 and the low level is 0, but in SIR send logic, the high level is 0 and the low level is 1.

11.6 DMA

The USART module supports DMA function, which can be used to achieve fast and continuous transmitting and receiving. When DMA is enabled, the DMA writes data from the set memory space to the transmit buffer when TXE is set. When using DMA to receive, each time RXNE is set, DMA transfers the data in the receive buffer to a specific memory space.

11.7 Interrupt

The USART module supports a variety of interrupt sources, including transmit data register empty (TXE), CTS, transmit complete (TC), receive data ready (RXNE), data overflow (ORE), line idle (IDLE), parity error (PE), disconnect flag (LBD), noise (NE), overflow for multi-buffered communication (ORT), and frame error (FE), among others.

| Interrupt source | Enable bit |
|------------------------------------|------------|
| Transmit data register empty (TXE) | TXEIE |
| CTS interrupt (CTS) | CTSIE |
| Transmission complete (TC) | TCIE |
| Receive data register not empty | |
| (data ready to be read) | RXNEIE |
| Overrun error detected (ORE) | |
| Idle line detected (IDLE) | IDLEIE |
| Parity error (PE) | PEIE |
| LIN break (LBD) | LBDIE |
| Noise flag (NE) | |
| Overflow of multi-buffered | |
| communication (ORT) | EIE |
| Frame error (FE) for multibuffered | |
| communication | |

Table 11-1 Relationship between interrupts and corresponding enable bits

| Bit | Name | Access | Description | Reset value |
|---------|----------|--------|---|-------------|
| [31:10] | Reserved | RO | Reserved | 0 |
| 9 | CTS | RW0 | CTS state change flag. If the CTSE bit is set, this bit will be set high by hardware when the nCTS output state changes. It is cleared to zero by | 0 |

| | | | software. If the CTSIE bit is already set, an | |
|---|------|-----|--|---|
| | | | interrupt will be generated. 1: There is a change on the nCTS status line; | |
| | | | 0: There is no change on the nCTS status line. | |
| 8 | | DWO | LIN Break detection flag. This bit is set by hardware when LIN Break is detected. Cleared by software. If LBDIE has been set, an interrupt will | 0 |
| 8 | LBD | RW0 | be generated. 1: LIN Break is detected; 0: LIN Break is not detected. | 0 |
| 7 | TXE | RO | Transmit data register empty flag. This bit is set by hardware when the data in the TDR register is transferred to the shift register by hardware. If TXEIE has been set, an interrupt will be generated and the data register will be written and this bit will be reset. 1: The data has been transferred to the shift register; 0: The data has not been transferred to the shift register. | 1 |
| 6 | TC | RW0 | Transmit completion flag. When a frame containing data is transmitted and TXE is set, the hardware will set this bit. If TCIE is set, a corresponding interrupt will be generated. The software will clear this bit after reading this bit and writing to the data register. You can also directly write 0 to clear this bit. 1: The transmitting is completed; 0: The transmitting is not yet completed. | 1 |
| 5 | RXNE | RW0 | Read the data register non-empty flag. When the data in the shift register is transferred to the data register, this bit will be set by hardware. If RXNEIE has been set, the corresponding interrupt will also be generated. Reading the data register clears this bit. You can also write 0 directly to clear this bit. 1: The data has been received and can be read; 0: The data has not been received yet. | 0 |
| 4 | IDLE | RO | Bus idle flag. This bit will be set by hardware when the bus is free. If IDLEIE has been set, the corresponding interrupt will be generated. Reading the status register and then the data register clears this bit. 1: Bus is idle; 0: Bus idle is not detected. <i>Note: This bit will not be set again until RXNE is</i> <i>set.</i> | 0 |
| 3 | ORE | RO | Overload error flag. This bit will be set when there is data in the receiving shift register that needs to be transferred to the data register, but there is still data in the receiving field of the data register that has not been read out. If RXNEIE is set, a corresponding interrupt will be generated. 1: An overload error occurs; 0: There is no overload error. Note: In case of an overload error, the value of the data register is not lost, but the value of the shift | 0 |

| 2 | NE | RO | register is overwritten. If the EIE able bit is set, the ORE flag position bit generates an interrupt in multi-buffer communication mode. Noise error flag. It is set by hardware when the noise error flag is detected. The operation of reading the status register and then reading the data register resets this bit. 1: Noise detected. 0: No noise is detected. Note: This bit does not generate an interrupt. If the EIE bit is set, the FE flag position bit generates an interrupt in multi-buffer communication mode. Frame error flag. This bit will be set by hardware | 0 |
|---|----|----|---|---|
| 1 | FE | RO | when a synchronization error, excessive noise or disconnect character is detected. Reading this bit and then reading the data register operation will reset this bit. 1: Frame error detected. 0: No frame error detected. Note: This bit will not generate an interrupt. If the EIE bit is set, the FE flag position bit will generate an interrupt in multi-buffer communication mode. | 0 |
| 0 | PE | RO | Check error flag. In receive mode, hardware sets this bit if a parity error occurs. Reading this bit and then reading the data register resets this bit. Software must wait for the RXNE flag to be set before clearing this bit. If PEIE has been set before, then setting this bit will generate a corresponding interrupt. 1: A parity error occurred; 0: No parity error. | 0 |

11.8.2 USART Data Register (USART_DATAR)

Offset address: 0x04

| [7:0] | PSC[7:0] | RW | Prescaler value range. In the infrared low-power mode, the source clock is divided by this value (all 8 bits are valid). When the value is 0, it means reserved; in the infrared normal mode, this bit can only be set to 1. | 0 |

Chapter 12 Inter-integrated Circuit (I2C) interface

The internal integrated circuit bus (I2C) is widely used for communication between microcontrollers, sensors and other off-chip modules. It supports multi-slave mode and can operate at 100KHz (standard) and 400KHz (fast) using only two wires (SDA and SCL). The I2C bus not only supports I2C timing, but also supports DMA function and CRC check function.

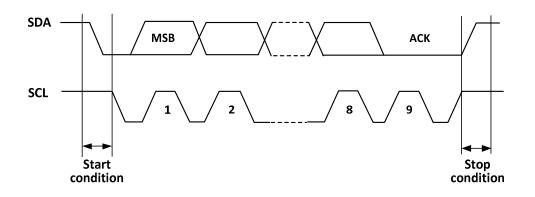

12.1 Main Features

- Support slave mode.
- Support 7-bit or 10-bit addresses.
- Slave devices support dual 7-bit addresses.
- Support two speed modes: 100KHz and 400KHz
- Various error flags
- Support extended clock function
- 2 interrupt vectors
- Support DMA, PEC

12.2 Overview

I2C is a half-duplex bus, which can only operate in one of the following two modes at the same time: slave sending mode and slave receiving mode. Both data and address are transmitted in units of 8 bits, with the high bit in front and the low bit in the back. After the start event is a byte (in 7-bit address mode) or two bytes (in 10-bit address mode) address, every time the master transmits 8 bits of data or address, the slave needs to reply with a response ACK, that is, pull the SDA bus low, as shown in Figure 12-1.

For normal use, the correct clock must be input to I2C. In standard mode, the minimum input clock is 2MHz, and in fast mode, the minimum input clock is 4MHz.

Figure 12-2 shows the functional block diagram of the I2C module.

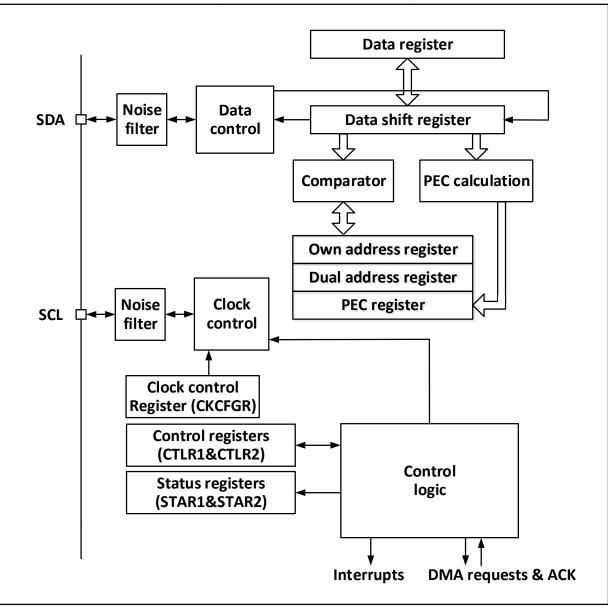

Figure 12-2 I2C functional block diagram

12.3 Slave Mode

In slave mode, the I2C module can recognize its own address and the general call address. The software can control whether to enable or disable the recognition of broadcast call addresses. Once a start event is detected, the I2C module compares the SDA data through the shift register with its own address (the number of bits depends on ENDUAL and ADDMODE) or the broadcast address (when ENGC is set). If there is no match, it will be ignored until generate a new start event; if it matches the header sequence, it will generate an ACK signal and wait for the address of the second byte; if the address of the second byte also matches or the full segment address matches in the case of a 7-bit address, So:

First generate an ACK response;

The ADDR bit is set, and if the ITEVTEN bit is set, a corresponding interrupt will be generated;

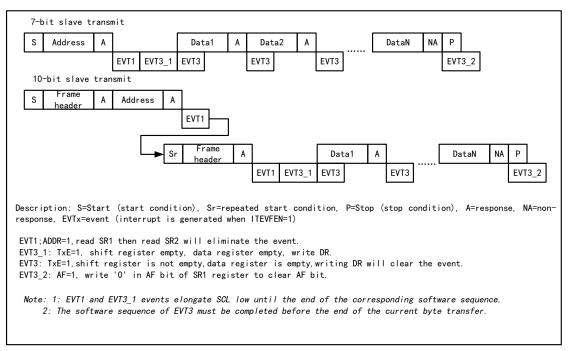

If you are using dual address mode (the ENDUAL bit is set), you also need to read the DUALF bit to determine which address is evoked by the host.

The default slave mode is the receive mode. After the last bit of the received header sequence is 1, or the last bit of

the 7-bit address is 1 (depending on whether the header sequence is received for the first time or an ordinary 7-bit address), when a repeated When the start condition is reached, the I2C module will enter the transmitter mode, and the TRA bit will indicate whether it is the receiver or transmitter mode.

Slave transmit mode:

After clearing the ADDR bit, the I2C module sends the byte from the data register through the shift register to the SDA line. The slave holds SCL low until the ADDR bit is cleared and the data to be transmitted has been written to the data register. (See EVT1 and EVT3 in the picture below). After receiving a response ACK, the TxE bit will be set, and if ITEVTEN and ITBUFEN are set, an interrupt will be generated. If TxE is set but no new data is written to the data register before the end of the next data transmission, the BTF bit will be set. Before clearing BTF, SCL will remain low. After reading status register 1 (R16_I2C_STAR1), writing data to the data register will clear the BTF bit.

Slave receive mode:

After ADDR is cleared, the I2C module stores the data on SDA into the data register through the shift register. After each byte is received, the I2C module sets an ACK bit and sets the RxNE bit. If ITEVTEN and ITBUFEN are set, an interrupt will also be generated. If RxNE is set and old data is not read before new data is received, BTF will be set. SCL will remain low until the BTF bit is cleared. Reading status register 1 (R16_I2C_STAR1) and reading the data in the data register will clear the BTF bit.

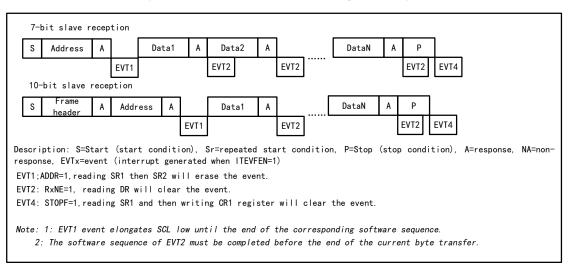

Figure 12-4 Receiver transmission sequence diagram

The master device will generate a stop condition after transmitting the last data byte. When the I2C module detects a stop event, the STOPF bit will be set. If the ITEVFEN bit is set, an interrupt will be generated. The user needs to read the status register (R16_I2C_STAR1) and then write the control register (such as the reset control word SWRST) to clear it. (See EVT4 in the picture above).

12.4 Error Conditions

12.4.1 Bus Error (BERR)

During the transfer of address or data, when the I2C module detects an external start or stop event, a bus error will be generated. When a bus error occurs, the BERR bit is set, and an interrupt is generated if ITERREN is set. In slave mode, data is discarded and the hardware releases the bus. If it is a start signal, the hardware will consider it a restart signal and start waiting for the address or stop signal; if it is a stop signal, it will operate according to normal stop conditions in advance.

12.4.2 Acknowledge Failure (AF)

When the I2C module detects a byte and does not respond, a response error occurs. When a response error occurs: AF will be set, and if ITERREN is set, an interrupt will be generated; when an AF error is encountered, the hardware must release the bus.

12.4.3 Overrun/Underrun Error (OVR)

• Overrun error

In slave mode, if clock extension is disabled and the I2C module is receiving data, if one byte of data has been received but the last received data has not been read out, an overload error will occur. When an overload error occurs, the last received byte will be discarded and the sender should resend the last byte sent.

• Underrun error

In slave mode, if clock stretching is disabled and the I2C module is sending data, if new data has not been written to the data register before the next byte clock arrives, an underrun error will occur. When an underrun error occurs, the data in the previous data register will be sent twice. If an underrun error occurs, the receiver should discard the duplicated data. In order not to generate an underrun error, the I2C module should write data to the data register

before the first rising edge of the next byte.

12.5 Clock Extension

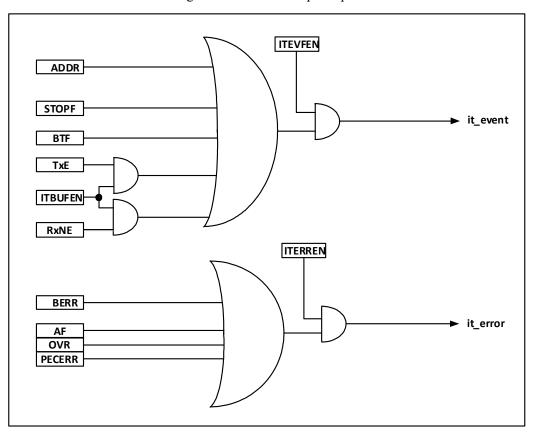

If clock stretching is disabled, there is a possibility of overrun/underrun errors. But if clock stretching is enabled:

- In transmit mode, if TxE is set and BTF is set, SCL will always be low, waiting for the user to read the status register and write the data to be sent to the data register;
- In receive mode, if RxNE is set and BTF is set, SCL will remain low after receiving data until the user reads the status register and reads the data register.

It can be seen that enabling clock stretching can avoid overload/underrun errors.

12.6 Interrupts

Each I2C module has two interrupt vectors, namely event interrupt and error interrupt. Two interrupts support the interrupt sources in Figure 12-5.

12.7 DMA

DMA can be used to transmit and receive batch data. The ITBUFEN bit of the control register cannot be set when using DMA.

• Transmit by DMA

DMA mode can be activated by setting the DMAEN bit in the CTLR2 register. As long as the TxE bit is set, data

will be loaded from the set memory into the I2C data register by DMA. The following settings are required to assign channels to I2C.

- 1) The I2C_DATAR register address is set to the DMA_PADDRx register and the memory address is set in the DMA_MADDRx register so that data will be sent from memory to the I2C_DATAR register after each TxE event.
- 2) Set the required number of bytes to transfer in the DMA_CNTRx register. After each TxE event, this value will be decremented.
- 3) Configure the channel priority using the PL[0:1] bits in the DMA_CFGRx register.
- 4) Set the DIR bit in the DMA_CFGRx register and configure an interrupt request to be issued when half or all of the entire transfer is completed, depending on the application requirements.
- 5) Activate the channel by setting the EN bit on the DMA_CFGRx register.

When the number of data transfer bytes set in the DMA controller has been completed, the DMA controller sends an end-of-transmission EOT/EOT_1 signal to the I2C interface. With interrupts enabled, a DMA interrupt will be generated.

• Receive by DMA

After setting DMAEN in the CTLR2 register, the DMA receive mode can be entered. When using DMA to receive, DMA transfers the data in the data register to the preset memory area. The following steps are required to assign channels to I2C.

- 1) Set the I2C_DATAR register address to the DMA_PADDRx register and the memory address in the DMA_MADDRx register so that data will be written from the I2C_DATAR register to the memory after each RxNE event.
- 2) Set the required number of bytes to transfer in the DMA_CNTRx register. After each RxNE event, this value will be decremented.
- 3) Configure the channel priority with PL[0:1] in the DMA_CFGRx register.
- 4) Clear the DIR bit in the DMA_CFGRx register. Depending on the application requirements, you can set an interrupt request to be issued when the data transfer is half or fully completed.
- 5) Setting the EN bit in the DMA_CFGRx register activates the channel.

When the number of data transfer bytes set in the DMA controller has been completed, the DMA controller sends an end-of-transmission EOT/EOT_1 signal to the I2C interface. With interrupts enabled, a DMA interrupt will be generated.

12.8 Packet Error Checking

Packet Error Checking (PEC) is a step that adds a CRC8 check to provide transmission reliability. It uses the following polynomial to calculate each bit of serial data:

$C = X^8 + X^2 + X + 1$

The PEC calculation is activated by the ENPEC bit of the control register and is calculated on all information bytes, including address and read and write bits. When sending, enabling PEC will add a byte of CRC8 calculation result after the last byte of data; while in receiving mode, the last byte is considered to be the CRC8 check result. If it does not match the internal calculation result, a NAK will be replied. If it is the main receiver, a NAK will be replied regardless of whether the verification result is correct or not.

12.9 Register Description

| Name | Access address | Description | Reset value |
|----------------|----------------|------------------------|-------------|
| R16_I2C_CTLR1 | 0x40005400 | I2C control register 1 | 0x0000 |
| R16_I2C_CTLR2 | 0x40005404 | I2C control register 2 | 0x0000 |
| R16_I2C_OADDR1 | 0x40005408 | I2C address register 1 | 0x0000 |
| R16_I2C_OADDR2 | 0x4000540C | I2C address register 2 | 0x0000 |
| R16_I2C_DATAR | 0x40005410 | I2C data register | 0x0000 |
| R16_I2C_STAR1 | 0x40005414 | I2C status register 1 | 0x0000 |
| R16_I2C_STAR2 | 0x40005418 | I2C status register 2 | 0x0000 |

Table 12-1 I2C-related registers list

12.9.1 I2C Control Register (I2C_CTLR1)

| 15 | 14 | 13 | 12 | 11 | 10 | 9 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| SWR ST | Rese | erved | PEC | POS | ACK | Reserved | NOS TRET CH | ENG C | ENPE C | | Rese | erved | | PE |

| Bit | Name | Access | Description | Reset value |
|---------|----------|--------|---|-------------|
| 15 | SWRST | RW | Software reset, user code setting this bit will reset the I2C peripheral. Before resetting, make sure that the pins of the I2C bus are released and the bus is in an idle state. <i>Note: This bit can reset the I2C module when no</i> <i>stop condition is detected on the bus but the busy</i> <i>bit is 1.</i> | 0 |
| [14:13] | Reserved | RO | Reserved | 0 |
| 12 | PEC | RW | Packet error detection enable bit, set this bit to enable packet error detection. User code can set or clear this bit; when the PEC is transmitted, a start or end signal is generated, or the PE bit is cleared to 0, the hardware clears this bit. 1: With PEC; 0: Without PEC. | 0 |
| 11 | POS | RW | The ACK and PEC position set bits can be set or cleared by user code. After PE is cleared, it can be cleared by hardware. 1: The ACK bit controls the ACK or NAK of the next byte received in the shift register. The next byte received in the PEC shift register is PEC; 0: The ACK bit controls the ACK or NAK of the byte currently being received in the shift register. The PEC; 0: The ACK bit controls the ACK or NAK of the byte currently being received in the shift register. The PEC bit indicates that the current byte in the shift register is PEC. Note: The usage of POS bit in 2-byte data reception is as follows: it must be configured before receiving. In order to NACK the second byte, the ACK bit must be cleared immediately after clearing the ADDR bit; in order to detect the PEC of the second byte, the PEC bit is configured after the ADDR bit is configured. | 0 |

| 10 | АСК | RW | Acknowledge enable bit. This bit can be set or cleared by user code. When the PE bit is set, this bit can be cleared by hardware. 1: Return a | 0 |
|-------|-----------|----|---|---|
| | | | response after receiving a byte; 0: No response. | 0 |
| [9:8] | Reserved | RO | Reserved | 0 |
| 7 | NOSTRETCH | RW | Disable clock stretching bit. This bit is used to disable clock stretching in slave mode when the ADDR or BTF flag is set until cleared by software. 1: Disable clock extension; 0: Enable clock extension. | 0 |
| 6 | ENGC | RW | Broadcast call enable bit, set this bit to enable broadcast call and respond to broadcast address 00h. | 0 |
| 5 | ENPEC | RW | PEC enable bit, set this bit to enable PEC calculation. | 0 |
| [4:1] | Reserved | RO | Reserved | 0 |
| 0 | РЕ | RW | I2C peripheral enable bit. 1: Enable the I2C module; 0: Disable the I2C module. | 0 |

| | | | detected. This information is still updated when | |
| 1 | BUSY | RO | the interface is disabled (PE=0). | 0 |
| | | | 1: The bus is busy: SDA or SCL is at low level; | |
| | | | 0: The bus is idle and there is no communication. | |
| 0 | Reserved | RO | Reserved | 0 |

Chapter 13 Electronic Signature (ESIG)

The electronic signature contains chip identification information: flash memory area capacity and unique identification. It is burned into the system storage area of the memory module by the manufacturer when leaving the factory, and can be read through SWD (SDI) or application code.

13.1 Function Description

Flash memory area capacity: Indicates the size that the current chip user application can use.

Unique identification: 96-bit binary code, unique to any microcontroller, users can only read and access it and cannot modify it. This unique identification information can be used as the security password, decryption key, product serial number, etc. of the microcontroller (product) to improve the system security mechanism or indicate identity information.

Users of the above content can perform read access in 8/16/32 bits.

13.2 Register Description

| | Table | 13-1 ESIG registers | |
|-----------------|----------------|--------------------------------|-------------|
| Name | Access address | Description | Reset value |
| R16_ESIG_FLACAP | 0x1FFFF7E0 | Flash memory capacity register | 0xXXXX |
| R32_ESIG_UNIID1 | 0x1FFFF7E8 | UID register 1 | 0xXXXXXXXX |
| R32_ESIG_UNIID2 | 0x1FFFF7EC | UID register 2 | 0xXXXXXXXX |
| R32 ESIG UNIID3 | 0x1FFFF7F0 | UID register 3 | 0xXXXXXXXXX |

13.2.1 Flash Capacity Register (ESIG_FLACAP)

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|---|-------|---------|---|---|---|---|---|---|---|
| | | | | | | | F_SIZ | E[15:0] | | | | | | | |

| Bit | Name | Access | Description | Reset value |
|--------|--------------|--------|--|-------------|
| [15:0] | F_SIZE[15:0] | RO | Flash memory capacity in Kbytes. Example: 0x0080 = 128 K bytes. | Х |

13.2.2 UID Register (ESIG_UNIID1)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|----|------------|----|----|----|----|----|------|---------|----|----|----|----|----|----|----|
| | | | | | | | U_ID | [31:16] | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | U_ID[15:0] | | | | | | | | | | | | | | |
| | | | | | | | | | | | | | | | |

| Bit | Name | Access | Description | Reset value |
|--------|------------|--------|----------------|-------------|
| [31:0] | U_ID[31:0] | RO | UID bits 0-31. | Х |

13.2.3 UID Register (ESIG_UNIID2)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|----|-------------|----|----|----|----|----|------|---------|----|----|----|----|----|----|----|
| | U_ID[63:48] | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | | | | | | | U_ID | [47:32] | | | | | | | |

| ĺ | Bit | Name | Access | Description | Reset value |
|---|--------|-------------|--------|-----------------|-------------|
| ĺ | [31:0] | U_ID[63:32] | RO | UID bits 32-63. | Х |

13.2.4 UID Register (ESIG_UNIID3)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|----|-------------|----|----|----|----|----|------|---------|----|----|----|----|----|----|----|
| | U_ID[95:80] | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | | | | | | | U_ID | [79:64] | | | | | | | |

| ĺ | Bit | Name | Access | Description | Reset value |
|---|--------|-------------|--------|-----------------|-------------|
| ĺ | [31:0] | U_ID[95:64] | RO | UID bits 64-95. | Х |

Chapter 14 Flash Memory and User Option Bytes

14.1 Flash Memory Organization

The internal flash memory organization structure of the chip is as follows:

| | | Thash memory organization stracture | | | |
|----------------------|----------------------|-------------------------------------|------------|--|--|
| Block | Name | Address Range | Size(byte) | | |
| | Page 0 | 0x0800 0000 - 0x0800 003F | 64 | | |
| | Page 1 | $0x0800\ 0040 - 0x0800\ 007F$ | 64 | | |
| Main | Page 2 | $0x0800\ 0080 - 0x0800\ 00BF$ | 64 | | |
| memory | Page 3 | $0x0800\ 00C0 - 0x0800\ 00FF$ | 64 | | |
| | | | | | |
| | Page 256 | 0x0800 3FC0 - 0x0800 3FFF | 64 | | |
| Information block | Startup program code | 0x1FFF F000 – 0x1FFF F77F | 2K-128 | | |
| DIOCK | User option byte | 0x1FFF F800 – 0x1FFF F83F | 64 | | |

| | Table | 14-1 | Flash | memory | organization | structure |
|--|-------|------|-------|--------|--------------|-----------|
|--|-------|------|-------|--------|--------------|-----------|

Note:

 The above-mentioned main memory area is used for user application storage and is write-protected in units of 1K bytes (16 pages). Except for the "manufacturer configuration word" area, which is factory-locked and inaccessible to users, other areas can be operated by users under certain conditions.

14.2 Flash Memory Programming and Safety

14.2.1 Program/Erase Methods

- Standard programming: This method is the default programming method (compatibility mode). In this mode, the CPU performs programming in a single 2-byte manner, and performs erase and whole-chip erase operations in a single 1K byte manner.
- Fast programming: This method uses page operation mode (recommended). After a specific sequence is unlocked, a single 64-byte programming, 64-byte erase, and 1K-byte erase are performed (standard 1K full-chip erase is also suitable for fast programming).

14.2.2 Security - Protection against Illegal Access (read, write, erase)

- Page write protection
- Read protection

When the chip is in read protection state:

- Main memory pages 0-32 (2K bytes) are automatically write-protected and are not controlled by the FLASH_WPR register; when the read-protected state is released, all main memory pages are controlled by the FLASH_WPR register.
- 2) The main memory cannot be erased or programmed in the system boot code area, SDI mode, and RAM area, except for full chip erasure. User selectable word area can be erased or programmed. If you try to remove read protection (program user words), the chip will automatically erase the entire user area.

Note: The internal RC oscillator (HSI) must be turned on when performing flash program/erase operations.

14.3 Register Description

| | | 0 | |
|-------------------------|----------------|---------------------------|-------------|
| Name | Access address | Description | Reset value |
| R32_FLASH_ACTLR | 0x40022000 | Control register | 0x00000000 |
| R32_FLASH_KEYR | 0x40022004 | FPEC key register | Х |
| R32_FLASH_OBKEYR | 0x40022008 | OBKEY register | Х |
| R32_FLASH_STATR | 0x4002200C | Status register | 0x00008000 |
| R32_FLASH_CTLR | 0x40022010 | Configuration register | 0x00008080 |
| R32_FLASH_ADDR | 0x40022014 | Address register | Х |
| R32_FLASH_OBR | 0x4002201C | Option byte register | 0x0XXXXXXXX |
| R32_FLASH_WPR | 0x40022020 | Write protection register | 0xFFFFFFFF |
| R32_FLASH_MODEKEYR | 0x40022024 | Extension key register | Х |
| R32_FLASH_BOOT_MODEKEYR | 0x40022028 | Unlock BOOT key register | Х |

Table 14-2 FLASH registers

14.3.1 Control Register (FLASH_ACTLR)

Offset address: 0x00

|--------|----------------|--------|---|-------------|
| [31:0] | MODEKEYR[31:0] | WO | Enter the following sequence to unlock BOOT area KEY1 = 0x45670123; KEY2 = 0xCDEF89AB. | Х |

14.4 Flash Operation Procedure

14.4.1 Read Operation

Direct addressing is performed in the general address space, and any read operation of 8/16/32-bit data can access

the contents of the flash memory module and obtain the corresponding data.

14.4.2 Unlock Flash Memory

After the system reset, the flash memory controller (FPEC) and FLASH_CTLR register will be locked and cannot be accessed. The flash memory controller module can be unlocked by writing the sequence to the FLASH_KEYR register.

Unlock sequence:

1) Write KEY1 = 0x45670123 to the FLASH_KEYR register (must operate KEY1 first);

2) Write KEY2 = 0xCDEF89AB to the FLASH_KEYR register (must operate KEY2 secondly).

The above operations must be performed sequentially and continuously. Otherwise, it is an error operation, which will lock the FPEC module and FLASH CTLR register and generate a bus error until the next system reset.

The flash memory controller (FPEC) and the FLASH_CTLR register can be locked again by setting the "LOCK" bit in the FLASH_CTLR register to 1.

14.4.3 Main Memory Standard Programming

Standard programming can write 2 bytes at a time. When the PG bit of the FLASH_CTLR register is '1', each time a halfword (2 bytes) is written to the flash memory address, a programming will be initiated. If any non-halfword data is written, FPEC will generate a bus error. During the programming process, the BSY bit is '1'. When programming is completed, the BSY bit is '0' and the EOP bit is '1'.

Note: When the BSY bit is '1', writing to any register is prohibited.

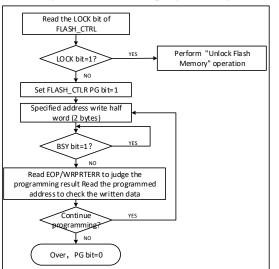

Figure 14-1 FLASH programming

- 1) Check the FLASH_CTLR register LOCK. If it is 1, you need to perform the "unlock flash memory" operation.
- 2) Set the PG bit of the FLASH_CTLR register to '1' to enable the standard programming mode.
- 3) Write the halfword to be programmed to the specified flash address (even address).
- 4) Wait for the BSY bit to become '0' or the EOP bit of the FLASH_STATR register to be '1' to indicate the end of programming, and clear the EOP bit to 0.
- 5) Query the FLASH_STATR register to see if there is an error, or read the programming address data for verification.
- 6) To continue programming, you can repeat steps 3-5 and end programming by clearing the PG bit to 0.

14.4.4 Main Memory Standard Erase

Flash memory can be erased in standard pages (1K bytes) or in its entirety.

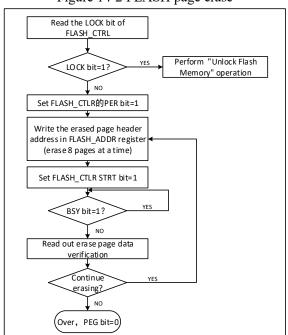

Figure 14-2 FLASH page erase

1) Check the LOCK bit of FLASH_CTLR register, if it is 1, you need to perform the "Unlock Flash" operation.

2) Set the PER bit of FLASH CTLR register to 'l' to enable the standard page erase mode.

3) Write the page header address to the FLASH_ADDR register to select the page to be erased.

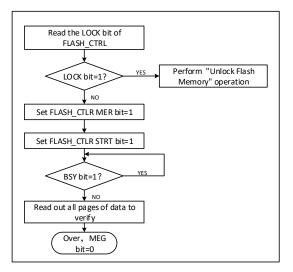

4) Set the STAT bit of FLASH_CTLR register to '1' to initiate an erase action.

5) Wait for the BYS bit to become '0' or the EOP bit of FLASH_STATR register to become '1' to indicate the end of erasure, and clear the EOP bit to 0.

6) Read the data of the erased page for verification.

7) Continue the standard page erase can repeat steps 3-5, end the erase to clear the PEG bit to 0.

Figure 14-3 FLASH whole chip erase

1) Check the LOCK bit of FLASH_CTLR register, if it is 1, you need to perform the "unlock flash memory" operation.

2) Set the MER bit of FLASH CTLR register to '1' to enable the whole chip erase mode.

3) Set the STAT bit of FLASH_CTLR register to '1' to start the erase operation.

4) Wait for the BYS bit to become '0' or the EOP bit of FLASH_STATR register to be '1' to indicate the end of erasure, and clear the EOP bit to 0.

5) Read the data of the erased page for verification.

6) Clear the MER bit to 0.

14.4.5 Fast Programming Mode Unlock

Fast programming mode operation can be unlocked by writing a sequence to the FLASH_MODEKEYR register. After unlocking, the FLOCK bit in the FLASH_CTLR register will clear to 0, indicating that fast erase and programming operations can be performed. The FLASH_CTLR register can be locked again by software setting the "FLOCK" bit to 1.

Unlock sequence:

- 1) Write KEY1 = 0x45670123 to FLASH_MODEKEYR register;
- 2) Write KEY2 = 0xCDEF89AB to FLASH_MODEKEYR register.

The above operations must be performed in sequence and continuously, otherwise the system will be locked due to incorrect operations and cannot be unlocked again until the next system reset.

Note: Fast programming operation requires unlocking both "LOCK" and "FLOCK" locks.

14.4.6 Main Memory Fast Programming

Fast programming programs by page (64 bytes).

- 1) Check the LOCK bit of the FLASH_CTLR register. If it is 1, you need to perform a "release flash lock" operation.
- 2) Check the BSY bit of the FLASH_STATR register to confirm that there are no other programming operations in progress.
- 3) Check the FLOCK bit of the FLASH_CTLR register. If it is 1, you need to perform a "fast programming mode unlock" operation.
- 4) Set the FTPG bit of the FLASH_CTLR register to enable the fast page programming mode function.
- 5) Set the BUFRST bit of the FLASH_CTLR register to perform a clear internal 64 byte buffer operation.
- 6) Wait for the BYS bit to become '0' or the EOP bit of the FLASH_STATR register to be '1' to indicate the end of clearing, clear the EOP bit to 0.
- 7) Start writing 4 bytes of data to the specified address (4 bytes/operation), and then Set the BUFLOAD bit of the FLASH_CTLR register to perform loading into the buffer area.
- 8) Wait for the BYS bit to become '0' or the EOP bit of FLASH_STATR register to become '1' to indicate the end of clearing, and clear the EOP bit to 0
- 9) Repeat steps 7-8 a total of 16 times to load all 64-byte data into the cache area (the addresses of the 16 rounds of operations must be consecutive).
- 10) Write the first address of the fast page programming to the FLASH_ADDR register.
- 11) Set the STAT bit of the FLASH_CTLR register to '1' to start a fast page programming action.
- 12) Wait for the BSY bit to become '0' or the EOP bit of FLASH_STATR register to become '1' to indicate the completion of one fast page programming and clear the EOP bit to 0.
- 13) Query the FLASH_STATR register to see if there is an error, or read the programming address data for verification.
- 14) To continue fast page programming, you can repeat steps 5-13 and end programming by clearing the FTPG bit to 0.

14.4.7 Main Memory Fast Erase

Fast erase erases by page (64 bytes).

- 1) Check the LOCK bit of the FLASH_CTLR register. If it is 1, you need to perform a "release flash lock" operation.
- 2) Check the FLOCK bit of the FLASH_CTLR register. If it is 1, you need to perform a "fast programming mode unlock" operation.
- 3) Check the BSY bit of the FLASH_STATR register to confirm that there are no other programming operations in progress.
- 4) Set the FTER bit of the FLASH_CTLR register to '1' to enable the fast page erase (64-byte) mode function.
- 5) Write the first address of the flash erase page to the FLASH_ADDR register.
- 6) Set the STAT bit of the FLASH_CTLR register to '1' to start a fast page erase (64 bytes) action.
- 7) Wait for the BSY bit to become '0' or the EOP bit of FLASH_STATR register to become '1' to indicate the end of erase, and clear the EOP bit to 0.
- 8) Query the FLASH_STATR register to see if there is an error, or read the erase page address data to verify.
- 9) To continue fast page erase, you can repeat steps 5-8 and end the erase by clearing the FTER bit to 0.

14.5 User Option Bytes

The user option byte is solidified in FLASH and will be reloaded into the corresponding register after the system is reset. The user can erase and program at will. The user selection word information block has a total of 8 bytes (4 bytes for write protection, 1 byte for read protection, 1 byte for configuration options, and 2 bytes for user data storage). Each bit has its complement bit is used for verification during the loading process. The selection word information structure and meaning are described below.

| Table 14-3 32-bit option byte format division | | | | | | | | | | |
|---|----------------|-----------------------------------|----------------|--|--|--|--|--|--|--|
| [31:24] | [23:16] | [15:8] | [7:0] | | | | | | | |
| Inverse code of option bytes 1 | Option bytes 1 | Inverse code of option bytes 0 | Option bytes 0 | | | | | | | |

| Address Bit | [31:24] | [23:16] | [15:8] | [7:0] |
|-------------|----------|----------|----------|----------|
| 0x1FFFF800 | nUSER | USER | nRDPR | RDPR |
| 0x1FFFF804 | nData1 | Data1 | nData0 | Data0 |
| 0x1FFFF808 | nWRPR1 | WRPR1 | nWRPR0 | WRPR0 |
| 0x1FFFF80C | Reserved | Reserved | Reserved | Reserved |

| | Name/B | yte | Description | Reset value |
|------|-----------|----------|--|-------------|
| RDPR | | | Read protection control. It configures whether the code in the flash memory can be read. 0xA5: If this byte is 0xA5 (nRDP must be 0x5A), it means that the current code is in a non-read protected state and can be read; Other values: Code read protection status, unreadable; pages 0 to 31 pages (4K) will be automatically write- protected and not controlled by WRPR0. | 0x01 |
| USER | [7:6] | Reserved | Reserved (must be 1) | 11b |
| USEK | 5 START_M | | Power-on startup method | 1 |

| | | ODE | | |
|----|-----------------------------|---------------|--|-------|
| | | ODE | Start from the BOOT area Start from the user area, the BOOT area can also place | |
| | | | user applications. | |
| | [4:3] RST_MOD E [1:0] | | PA6 is multiplexed as an external reset pin NRST. O0: Enable the multiplexing function, and the power-on reset will ignore the pin status within 128μs; O1: Enable the multiplexing function, and the power-on reset will ignore the pin status within 1ms; 10: Enable the multiplexing function, and the power-on reset will ignore the pin status within 12ms; 11: Multiplexing function Closed, PA6 has IO function. | 11b |
| | 2 | STANDYR ST | System reset control in standby mode:1: Disabled, the system does not reset when entering standby mode;0: Enabled, system reset occurs when entering standby mode. | 1 |
| | 1 | Reserved | Reserved | 1 |
| | 0 | Reserved | Reserved | 1 |
| I | Data0D | atal | Stores 2 bytes of user data. | FFFFh |
| WF | RPR0 - V | VRPR3 | Write protection control bit. Each bit is used to control the write protection status of 1 sector (1K bytes/sector) in main memory. 1: Enable write protection; 0: Enable write protection. 2 bytes are used to protect a total of 16K bytes of main memory. WRPO: Sectors 0-7 store write protection control; WRP1: Sectors 8-15 store write protection control; WRP2: Reserved; WRP3: Reserved. | FFFFh |

14.5.1 User Option Bytes Unlock

User option byte operation can be unlocked by writing a sequence to the FLASH_OBKEYR register. After unlocking, the OBWRE bit of the FLASH_CTLR register will be set to 1, indicating that erasing and programming of user-selected words can be performed. Lock again by clearing the "OBWRE" bit of the FLASH_CTLR register to 0 by software.

Unlock sequence:

1) Write KEY1 = 0x45670123 to the FLASH_OBKEYR register;

2) Write KEY2 = 0xCDEF89AB to the FLASH_OBKEYR register.

Note: The user needs to unlock the 2 layers: "LOCK" and "OBWRE" for word selection.

14.5.2 User Option Bytes Programming

Only supports standard programming, writing half word (2 bytes) at a time. In the actual process, when programming the user option byte, FPEC only uses the low byte in the half word, and automatically calculates the high byte (the high byte is the complement of the low byte), and then starts the programming operation, which will It is guaranteed that the byte in the user-selected word and its complement are always correct.

- 1) Check the LOCK bit of the FLASH_CTLR register. If it is 1, you need to perform the "unlock flash lock" operation.
- 2) Check the BSY bit of the FLASH_STATR register to confirm that there are no other programming operations in progress.

- 3) Check the OBWRE bit of the FLASH_CTLR register. If it is 0, the "user selected word unlock" operation needs to be performed.
- 4) Set the OBPG bit of the FLASH_CTLR register to '1'.
- 5) Write the halfword (2 bytes) to be programmed to the specified address.
- 6) Wait for the BYS bit to become '0' or the EOP bit of the FLASH_STATR register to be '1' to indicate the end of programming, and clear the EOP bit to zero.
- 7) Read programming address data verification.
- 8) To continue programming, you can repeat steps 5-7 and end programming by clearing the OBPG bit to 0.

Note: When the "read protection" in the modified selection word changes to the "unprotected" state, a full chip erase operation of the main storage area will be automatically performed. If you modify the selection other than "read protection", the entire chip erase operation will not occur.

14.5.3 User Option Bytes Erase

Directly erase the entire 64-byte user option byte area.

- 1) Check the LOCK bit of the FLASH_CTLR register. If it is 1, you need to perform a "release flash lock" operation.
- 2) Check the BSY bit of the FLASH_STATR register to confirm that no programming operation is in progress.
- 3) Check the OBWRE bit of the FLASH_CTLR register. If it is 0, the "user option byte unlock" operation needs to be performed.
- 4) Set the OBER bit of the FLASH_CTLR register to '1' and later set the STAT bit of the FLASH_CTLR register to '1' to enable user option byte erase.
- 5) Wait for the BYS bit to become '0' or the EOP bit of the FLASH_STATR register to be '1' to indicate the end of erasure, and clear the EOP bit to zero.
- 6) Read erase address data verification.
- 7) End clears the OBER bit to 0.

14.5.4 Release Read Protection

Whether the flash memory is read-protected or not is determined by the user option byte. Read the FLASH_OBR register. When the RDPRT bit is '1', it means that the current flash memory is in the read protection state, and the flash memory operation is subject to a series of security protections in the read protection state. The process of lifting read protection is as follows:

- 1) Erase the entire user option byte area. At this time, the read protection field RDPR is still valid.
- 2) The user selects word programming and writes the correct RDPR code 0xA5 to release the read protection of the flash memory. (This step will first cause the system to automatically perform a full chip erase operation on the flash memory)
- 3) Perform a power-on reset to reload the selection byte (including the new RDPR code), and the read protection is released at this time.

14.5.5 Release Write Protection

Whether the flash memory is write-protected or not is determined by the user option byte. Read the FLASH_WPR register. Each bit represents 4K bytes of flash memory space. When the bit is '1', it indicates non-write protection status, and when it is '0', it indicates write protection. The process of removing write protection is as follows:

- 1) Erases the entire user option byte area.
- 2) Write the correct RDPR code 0xA5 to allow read access.

3) Perform a system reset, reload the selection bytes (including the new WRPR[3:0] bytes), and the write protection is released.

Chapter 15 USB PD Controller (USBPD)

15.1 Introduction to USB PD Controller

The chip has a built-in USB Power Delivery controller and PD transceiver PHY, and provides 3 CC pins, of which PB0/CC1R and PB9/CC3R pins have built-in type-C specification-defined controllable Rd pull-down resistors, and PB1/CC2 pins do not provide Rd by default, and customization can be supported.

Support USB Type-C master-slave detection, automatic BMC codec and CRC, hardware edge control, USB PD2.0 and PD3.0 power transfer control, fast charging, UFP/PD Sink and DFP/PD Source application, DRP application and dynamic switching. Built-in USB Type-C interface, supports master-slave detection, DRP, Sink/Consumer and Source/Provider.

- Built-in USB PD transceiver PHY with integrated hardware edge-slope control;
- Built-in USB Power Delivery controller, automatic BMC codec, 4b5b codec and CRC;
- Support SOP, SOP', SOP'' PD packets and USB PD reset signal frame hardware reset;
- Support maximum packet length of 510 bytes, DMA;
- Support USB PD 2.0 and 3.0 power transfer protocols, USB port supports BC and other charging protocols.
- Support comparator and multiple optional negative input reference voltages, programmable pull-up current

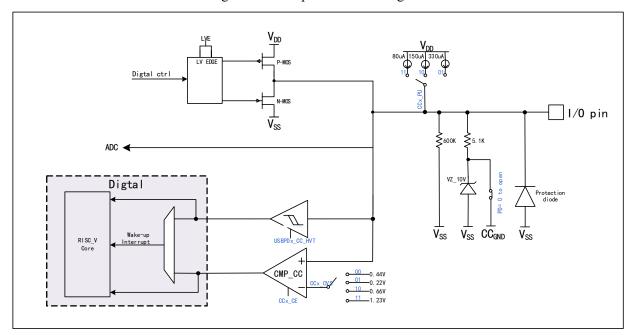

Figure 15-1 CC port structure diagram

Note: CCGND is the internal GND of CCx. If CCx has suffix R, that is, CCxR, its CCGND has been shorted to VSS inside the chip.

15.2 Register Description

| Table 15-1 U | USBPD-related | registers |
|--------------|---------------|-----------|
|--------------|---------------|-----------|

| Name | Access address | Description | Reset value |
|------------------|----------------|------------------------------|-------------|
| R32_USBPD_CONFIG | 0x40024000 | PD configuration register | 0x00000002 |

Chapter 16 BC/Differential amplification/QII/Extended Configuration (EXTEN)

16.1 Extended Configuration

The system provides three EXTEN expansion configuration units (EXTEN_CTLR0 register, EXTEN_CTLR1 register, EXTEN_CTLR2 register). This unit uses the HB clock and only performs reset actions during system reset. The EXTEN_CTLR0 register includes the LOCKUP function monitoring function: enabling the LKUPEN field will turn on the system's Lock-up situation monitoring. Once a Lock-up situation occurs, the system will perform a software reset and set the LKUPRST field to 1. After reading, you can write 1 to clear this logo.

The EXTEN_CTLR1 register includes the control bits for the BC interface UDM/UDP pins, the DAC and DAC_BUF output buffers/comparators, and the port pull-up/pull-down current.

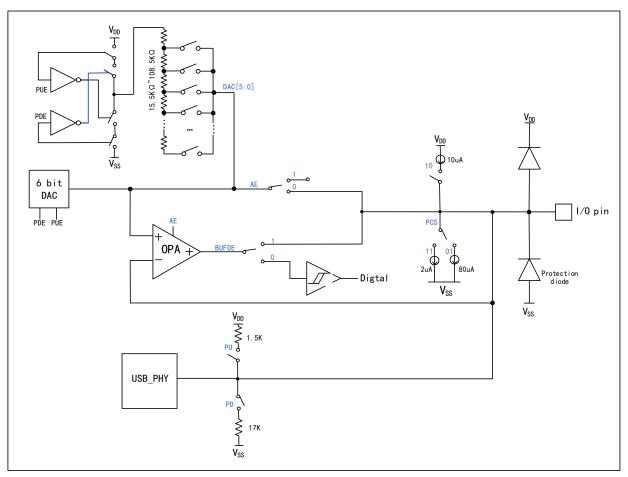

The EXTEN_CTLR2 register includes control bits for differential input current sampling (ISP), AC small signal amplification decoder (QII), and auxiliary control bits for USBPD and CC pins.

Each pin of the BC interface contains a 6-bit DAC and an output buffer DAC_BUF. Among them, the DAC can not only output a programmable voltage, but also realize the pull-up or pull-down of the programmable resistor; DAC_BUF can not only buffer the DAC voltage and output it to the pin, but can also be used as an analog voltage comparator to compare the pin voltage with the DAC voltage.

Differential input current sampling will be an external resistor to capture the current obtained by the weak voltage signal through the closed-loop amplifier ISP_OP amplified results through the ADC_IN8 channel into the ADC, ADC sampling results can be used for upper limit comparisons, calculations and analysis.

AC small signal amplifier decoder includes the adjustable gain amplifier QII_OP in the front stage and the voltage comparator QII_CMP in the back stage, which can amplify the input AC small signal, shape it into a digital signal, filter it and decode it after processing, and the decoded result is sent to ADC for sampling through ADC IN9 channel.

16.2 Function Description

As shown in the BC interface structure diagram in Figure 16-1, the following modes can be configured through the UDM/UDP corresponding control bits in the EXTEN_CTLR1 register:

DAC mode

1. When PDE=1, PUE=1, AE=0, DAC[5:0] input data, BUFOE=0, this is the DAC mode without buffer.

2. When PDE=1, PUE=1, AE=1, DAC[5:0] input data, BUFOE=1, this is DAC mode with buffer.

The DAC mode output voltage DAC_OUT is:

```
DAC OUT=DAC[5:0]*VDD33/64
```

CMP mode

When PDE=1, PUE=1, AE=1, DAC[5:0] inputs data, and BUFOE=0, it is in CMP mode. The input of the positive terminal of the CMP is DAC_OUT, the input voltage of the negative terminal of the CMP is IO port, and the output signal of the CMP is sent to the digital terminal.

Pull-up/pull-down resistor mode

1. When PDE=0, PUE=1, AE=0, DAC[5:0] input data, BUFOE=0, this is the programmable pull-up resistor mode. Where, when DAC[5:0]=000001, the pull-up resistor is equal to 7*RDAC (about 108.5k Ω), and when DAC[5:0]=111111, the pull-up resistor is equal to 1366/1365*RDAC (about 15.5k Ω).

2. When PDE=1, PUE=0, AE=0, DAC[5:0] input data, BUFOE=0, this is programmable pull-down resistor mode.

In this case, when DAC[5:0]=000000, the pull-down resistor is equal to RDAC (about 15.5k Ω), and when DAC[5:0]=111111, the pull-down resistor is equal to 7*RDAC (about 108.5k Ω). Note: See Table 16-1 for pull-up/down resistor resistance values.

Pull-up/pull-down current mode

- 1. When PCS = 10, this time for the weak pull-up current IPU2, about 10uA.
- 2. When PCS = 11, this time for the weak pull-down current IPD3, about 2uA.
- 3. When PCS = 01, this time for the weak pull-down current IPD1, about 80uA.

| DAC<5:0> | Pull-up resistor value (KΩ) | Pull-down resistor value (KΩ) | DAC<5:0> | Pull-up resistor value (KΩ) | Pull-down resistor value (KΩ) |

| 4 | Reserved | RO | Reserved | 0 |

| 3 | QII_HYP | RW | Signal decoding comparator QII_CMP hysteresis voltage selection: 1: Option 2; 0: default value, rated 200mV. <i>Note: Please refer to the data sheet "CH641DS0" for</i> <i>specific data.</i> | 0 |
|---|---------|----|--|---|
| 2 | QII_AV | RW | Signal decoding amplifier QII_OP gain selection: 1: Higher closed-loop gain, about 23 times; 0: Lower closed-loop gain, about 15 times. | 0 |
| 1 | QII_PS | RW | Signal decoding amplifier QII_OP input channel selection: 1: PA7 as input; 0: PB8 as input. | 0 |
| 0 | QII_AE | RW | Signal decoding amplifier QII_OP and comparator QII_CMP enable: 1: Enable the amplifier and comparator, use the output of the comparator as the input of the GPIO pin; 0: Disable the amplifier and comparator, input directly from GPIO. | 0 |

Chapter 17 Debug Support (DBG)

17.1 Main Features

This register allows configuration of the MCU in debug state. include:

- Support counter of Window Watchdog (WWDG)
- Support counter of Timer 1
- Support counter of Timer 2

17.2 Register Description

17.2.1 Debug MCU Configuration Register (DBGMCU_CTRL)

Address: 0x7C0(CSR)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Name | Access | Description | Reset value |
|---------|-----------|--------|---|-------------|
| [31:14] | Reserved | RW | Reserved | 0 |
| 13 | TIM2_STOP | RW | Timer 2 debug stop bit. The counter stops working when the core enters debug state.1: The counter of timer 2 stops working;0: The counter of timer 2 still works normally. | 0 |
| 12 | TIM1_STOP | RW | Timer 1 debug stop bit. The counter stops working when the core enters debug state.1: The counter of timer 1 stops working;0: The counter of timer 1 still works normally. | 0 |
| [10:11] | Reserved | RW | Reserved | 0 |
| 9 | WWDG_STOP | RW | Window watchdog debugging stop bit. The debug window watchdog stops working when the core enters debug state.1: The window watchdog counter stops working;0: The window watchdog counter still works normally. | |
| [8:3] | Reserved | RW | Reserved | 0 |
| 2 | STANDBY | RW | Debug standby mode bit. 1: (FCLK on, HCLK on) The digital circuit part is not powered off, and the FCLK and HCLK clocks are provided by the internal RL oscillator. In addition, the microcontroller exits STANDBY mode by generating a system reset, which is the same as reset; 0: (FCLK off, HCLK off) The entire digital circuit section is powered off. From a software point of view, exiting STANDBY mode is the same as resetting (except that some status bits indicate that the microcontroller has just exited STANDBY state). | 0 |
| 1 | Reserved | RW | Reserved | 0 |
| 0 | SLEEP | RW | Debug sleep mode bit. | 0 |

| 1: (FCLK on, HCLK on) In sleep mode, FCLK and HCLK clocks are provided by the originally configured system clock; 0: (FCLK on, HCLK off) In sleep mode, FCLK is provided by the originally configured system clock. clock is provided and HCLK is turned off. Since sleep mode does not reset the configured clock system, software does not need to reconfigure the clock system when exiting from sleep mode. | |
