

# CH32V00X Reference Manual

V1.1

<https://wch-ic.com>

## Overview

CH32V00X series are industrial-grade general-purpose microcontrollers designed based on 32-bit RISC-V instruction set and architecture. It adopts QingKe V2C core, RV32EC instruction set, and supports 2 levels of interrupt nesting. The series are mounted with rich peripheral interfaces and function modules. Its internal organizational structure meets the low-cost and low-power embedded application scenarios.

This manual provides detailed information on the use of the CH32V00X series for the user's application development, and is applicable to products with different memory capacities, functional resources, and packages in the series; any differences will be specially explained in the corresponding functional chapters.

Refer to the following datasheets for device characteristics of this series.

CH32V002: *CH32V002DS0*

CH32V004: *CH32V004DS0*

CH32V005, CH32V006: *CH32V006DS0*

CH32V007, CH32M007: *CH32V007DS0*

*For information about the core, refer to the QingKeV2 Microprocessor Manual, QingKeV2\_Processor\_Manual.*

### RISC-V core version overview

| Features<br>Core<br>versions | Instruction<br>set | Hardware<br>stack<br>levels | Interrupt<br>nesting<br>levels | Fast<br>interrupt<br>channels | Flow line | Vector table<br>model | Extensions<br>instruction | Debug<br>interface |
|------------------------------|--------------------|-----------------------------|--------------------------------|-------------------------------|-----------|-----------------------|---------------------------|--------------------|
| QingKe<br>V2C                | RV32EmC            | 2                           | 2                              | 2                             | 2         | Address or<br>command | Support                   | 1-wire             |

*Note: The "m" extension in RV32EmC implements the multiplication subset of the M extension.*

### Abbreviated description of the bit attribute in the register:

| Register bit<br>properties | Property description  |
|----------------------------|---|
| RF                         | Read-only property that reads a fixed value.                  |
| RO                         | Read-only attribute, changed by hardware.                     |
| RZ                         | Read-only property, auto bit clear 0 after read operation.    |
| WO                         | Write-only attribute (not readable, read value uncertain)     |
| WA                         | Write-only attribute, writable in Safe mode.                  |
| WZ                         | Write-only attribute, auto bit clear 0 after write operation. |
| RW                         | Readable and writable.  |
| RWA                        | Readable, writable in Safe mode.                              |
| RW1                        | Readable, write 1 is valid, write 0 is invalid.               |
| RW0                        | Readable, write 0 valid, write 1 invalid.                     |

|      |   |
|------|---|
| RW1T | Readable, write 0 invalid, write 1 flipped. |
|------|---|

# Chapter 1 Memory and Bus Architecture

## 1.1 Bus Architecture

CH32V00X series products are designed based on RISC-V instruction set, and its architecture realizes the interaction of core, arbitration unit, DMA module, SRAM memory and other parts through multiple buses. The design integrates a general-purpose DMA controller to reduce the burden on the CPU and improve the access efficiency, while at the same time, it also has a data protection mechanism, automatic clock switching protection, and other measures to increase the stability of the system.

Figure 1-1 CH32V002 system block diagram

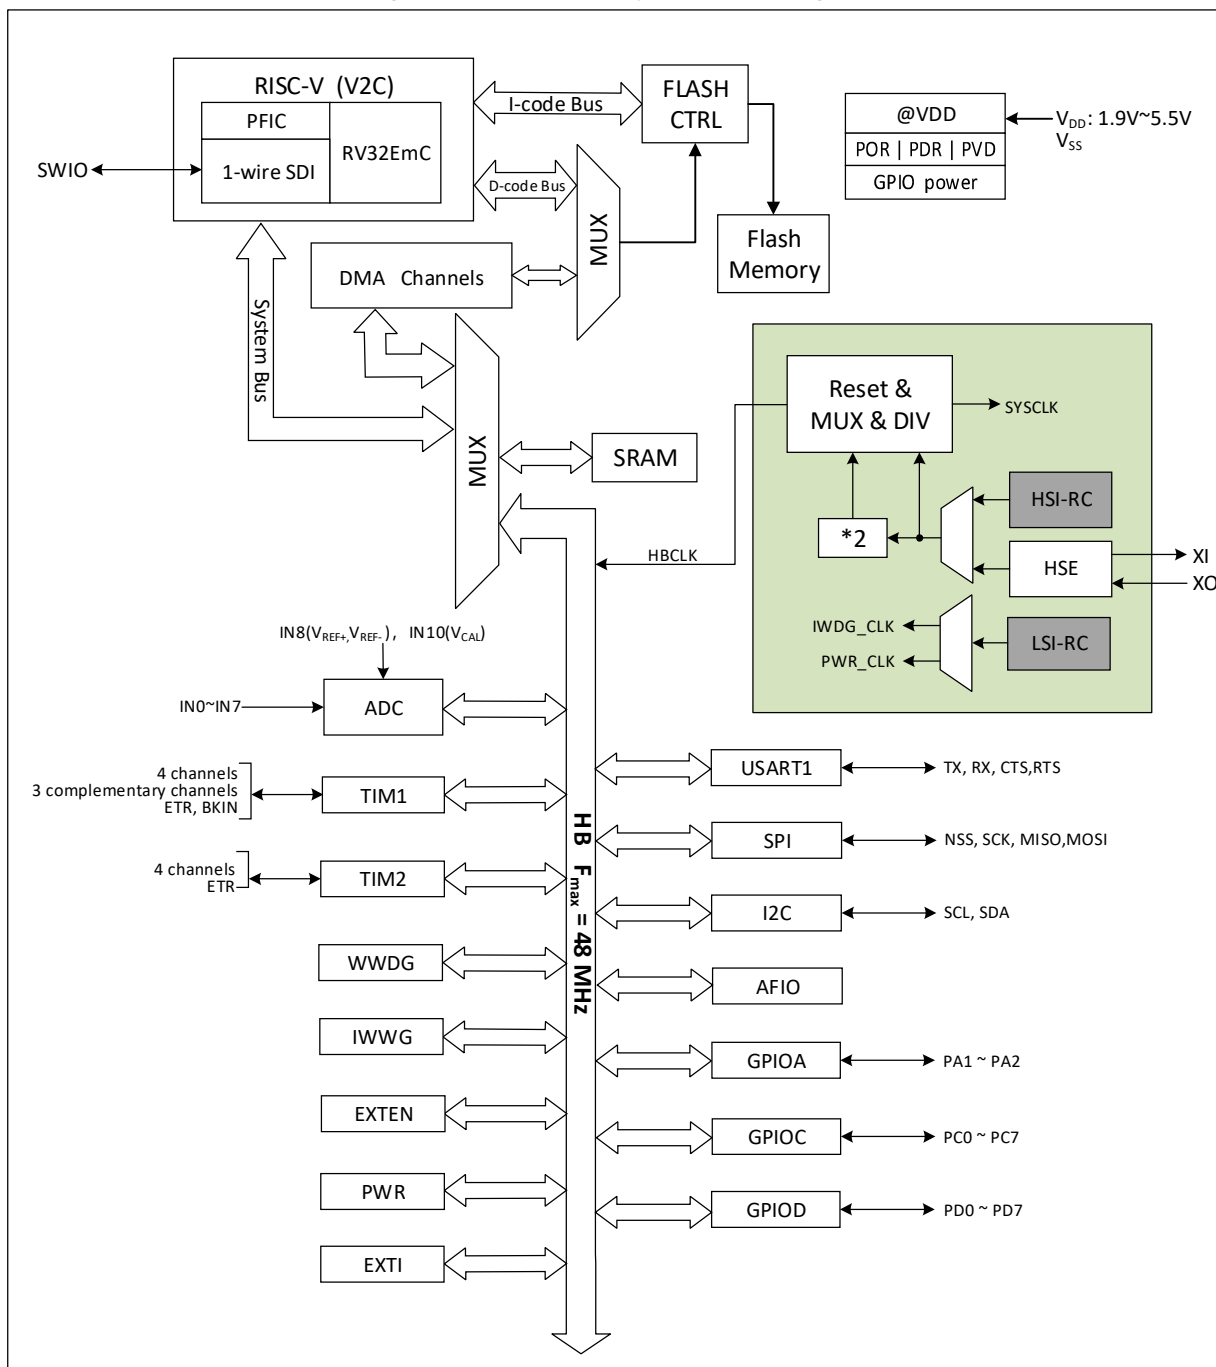

Figure 1-2 CH32V004 system block diagram

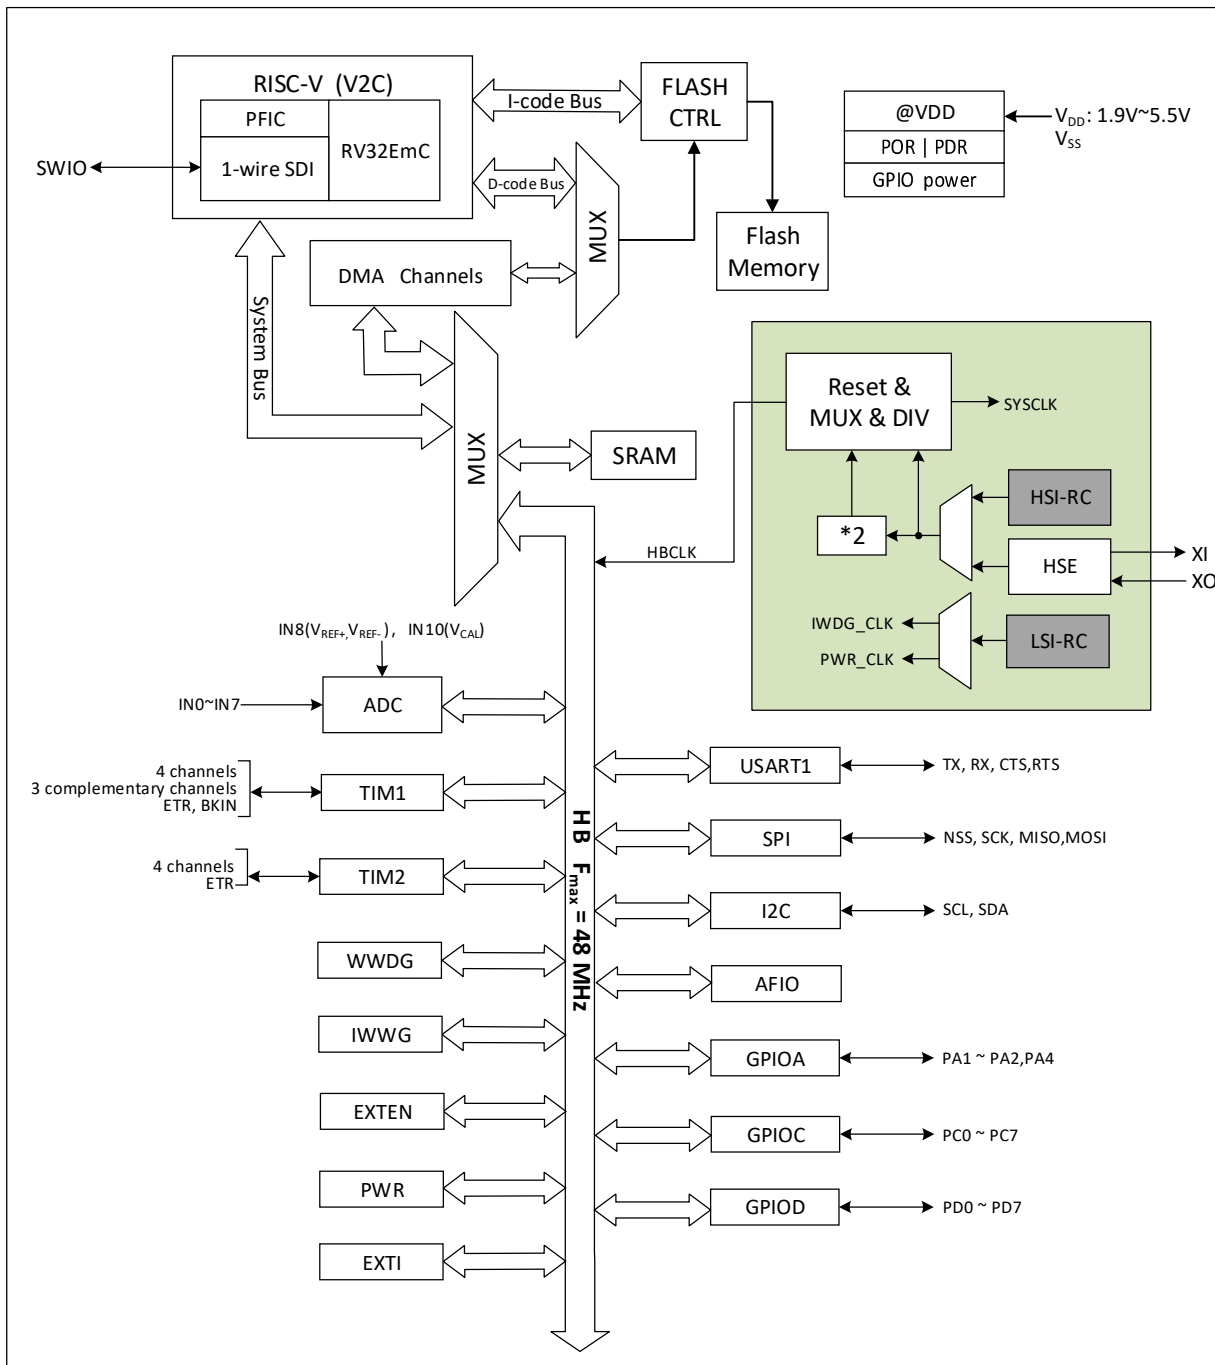

Figure 1-3 CH32V005, CH32V006 system block diagram

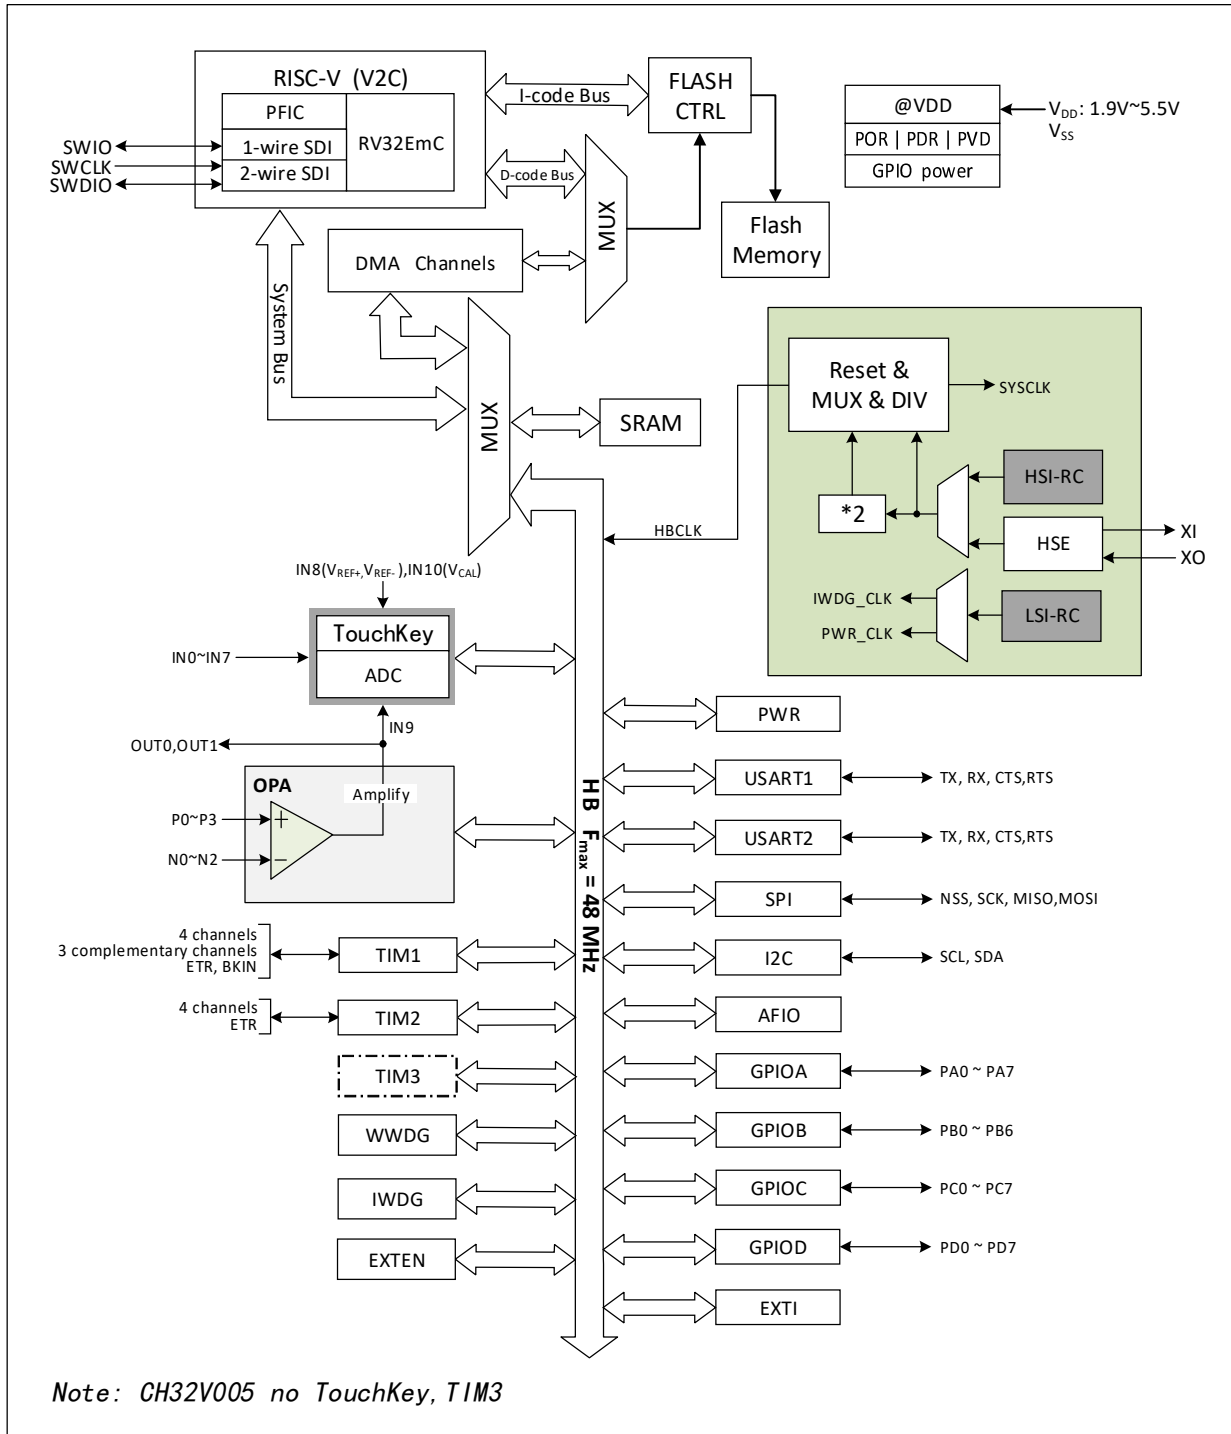

Figure 1-3 CH32V007 system block diagram

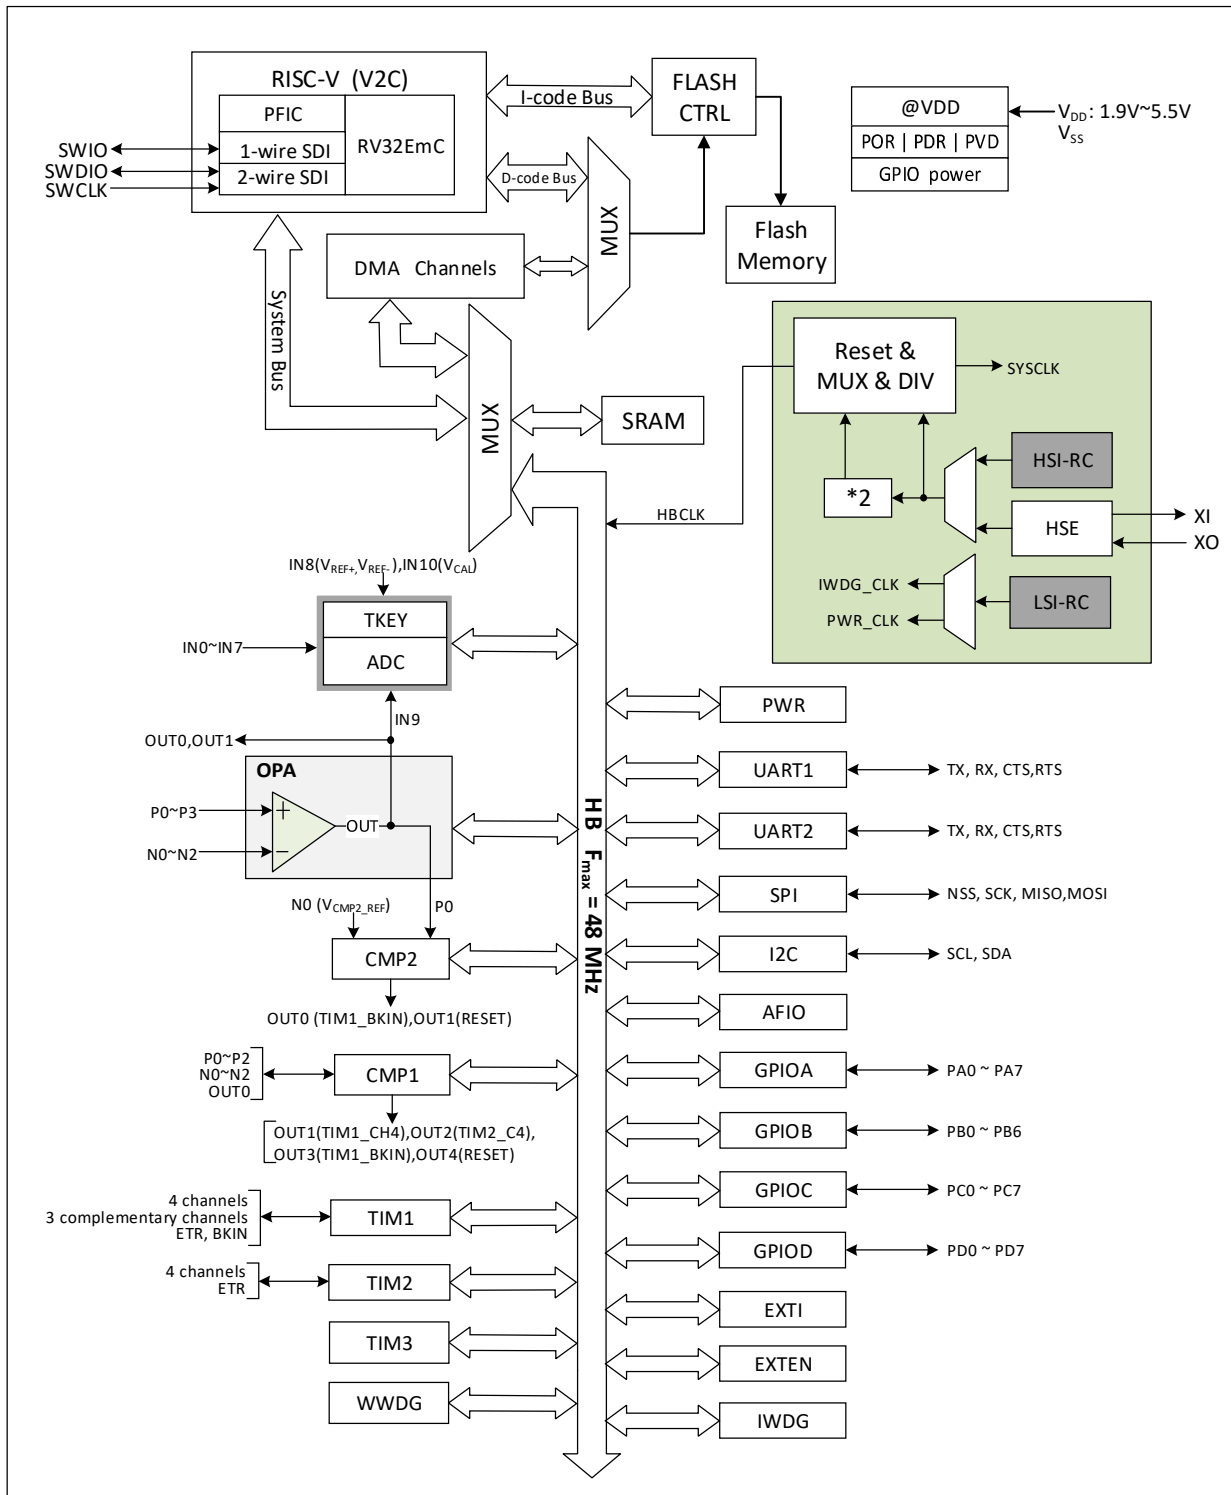

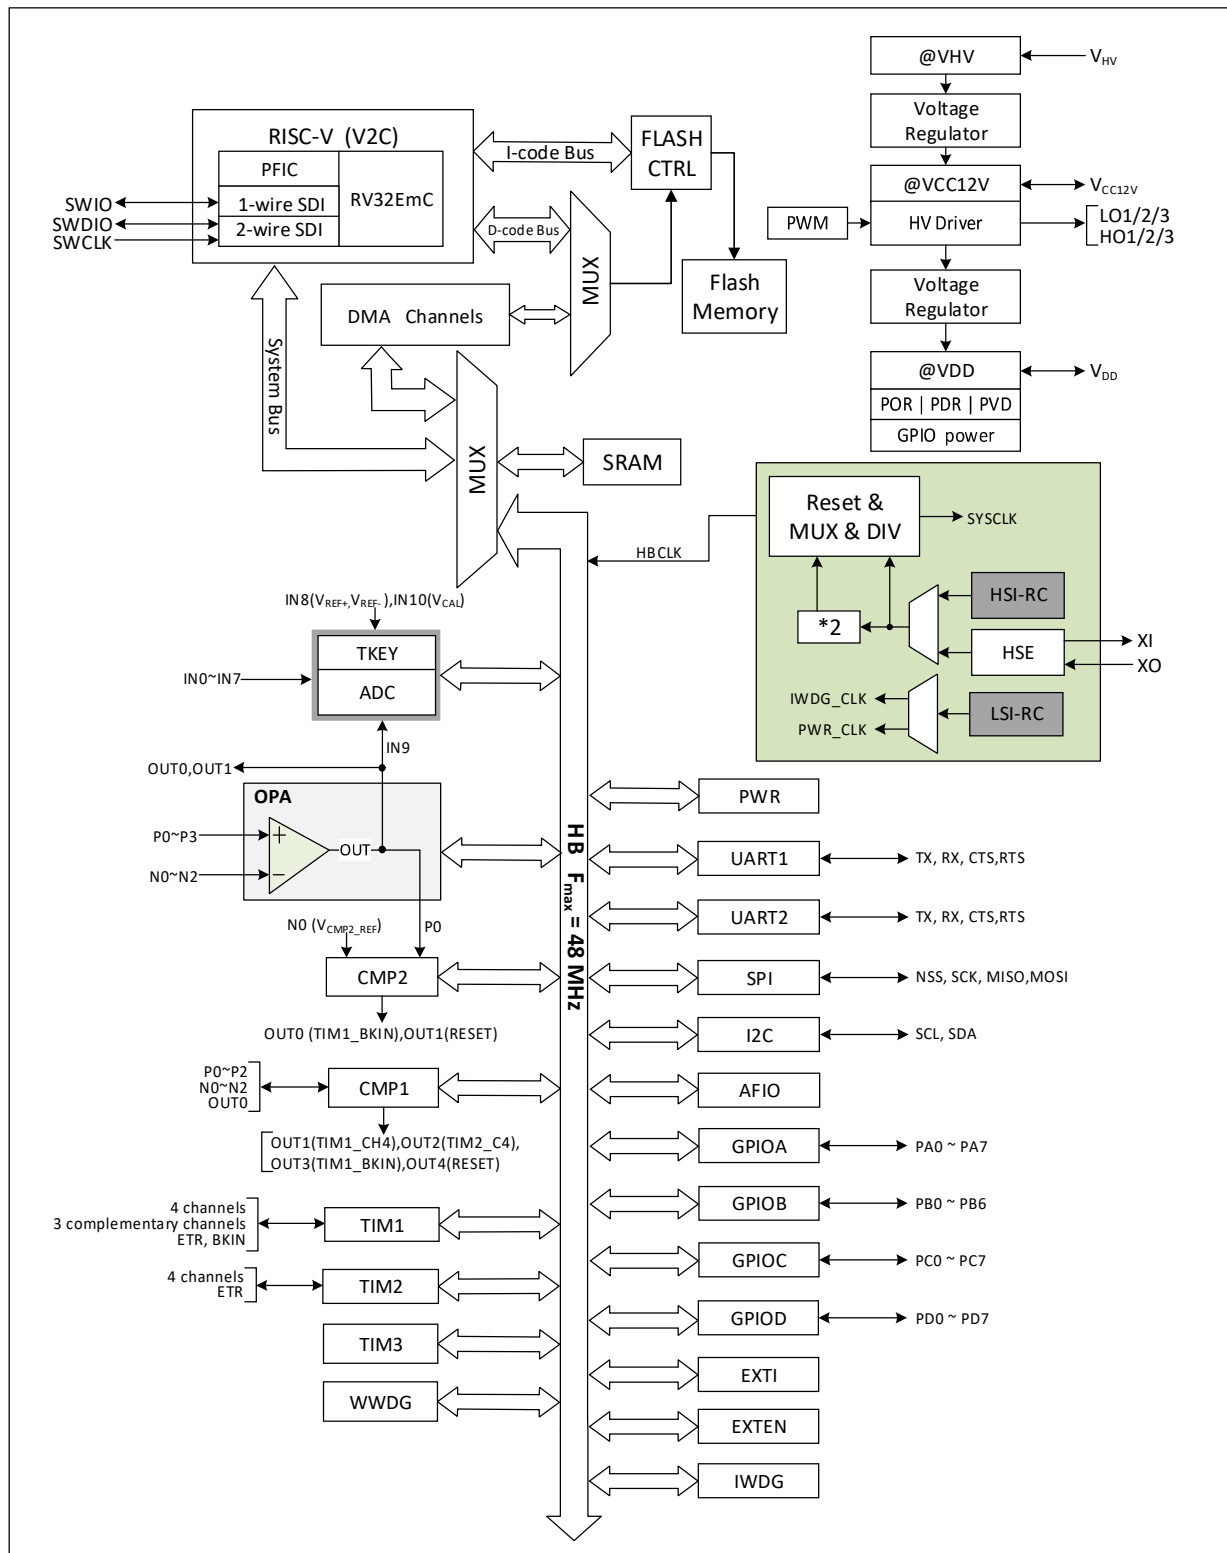

Figure 1-5 CH32M007 system block diagram

The system is equipped with a general DMA controller to reduce the burden of CPU and improve efficiency, and clock tree hierarchical management to reduce the total power consumption of peripherals, as well as data protection mechanism, clock security system protection mechanism and other measures to increase system stability.

- The instruction bus (I-Code) connects the core to the FLASH instruction interface and prefetching is done on this bus.
- The data bus (D-Code) connects the core to the FLASH data interface for constant loading and debugging.

- The system bus connects the core to the bus matrix and is used to coordinate accesses to the core, DMA, SRAM and peripherals.
- The DMA bus is responsible for the DMA of the HB master interface connected to the bus matrix, which is accessed by FLASH data, SRAM and peripherals.
- The bus matrix is responsible for the access coordination between the system bus, data bus, DMA bus, SRAM and HB bridge.

## 1.2 Memory Image

The CH32V00X family contains program memory, data memory, core registers, peripheral registers, and more, all addressed in a 4GB linear space.

System storage stores data in small-end format, i.e., low bytes are stored at the low address and high bytes are stored at the high address.

Figure 1-6 CH32V002 Storage image

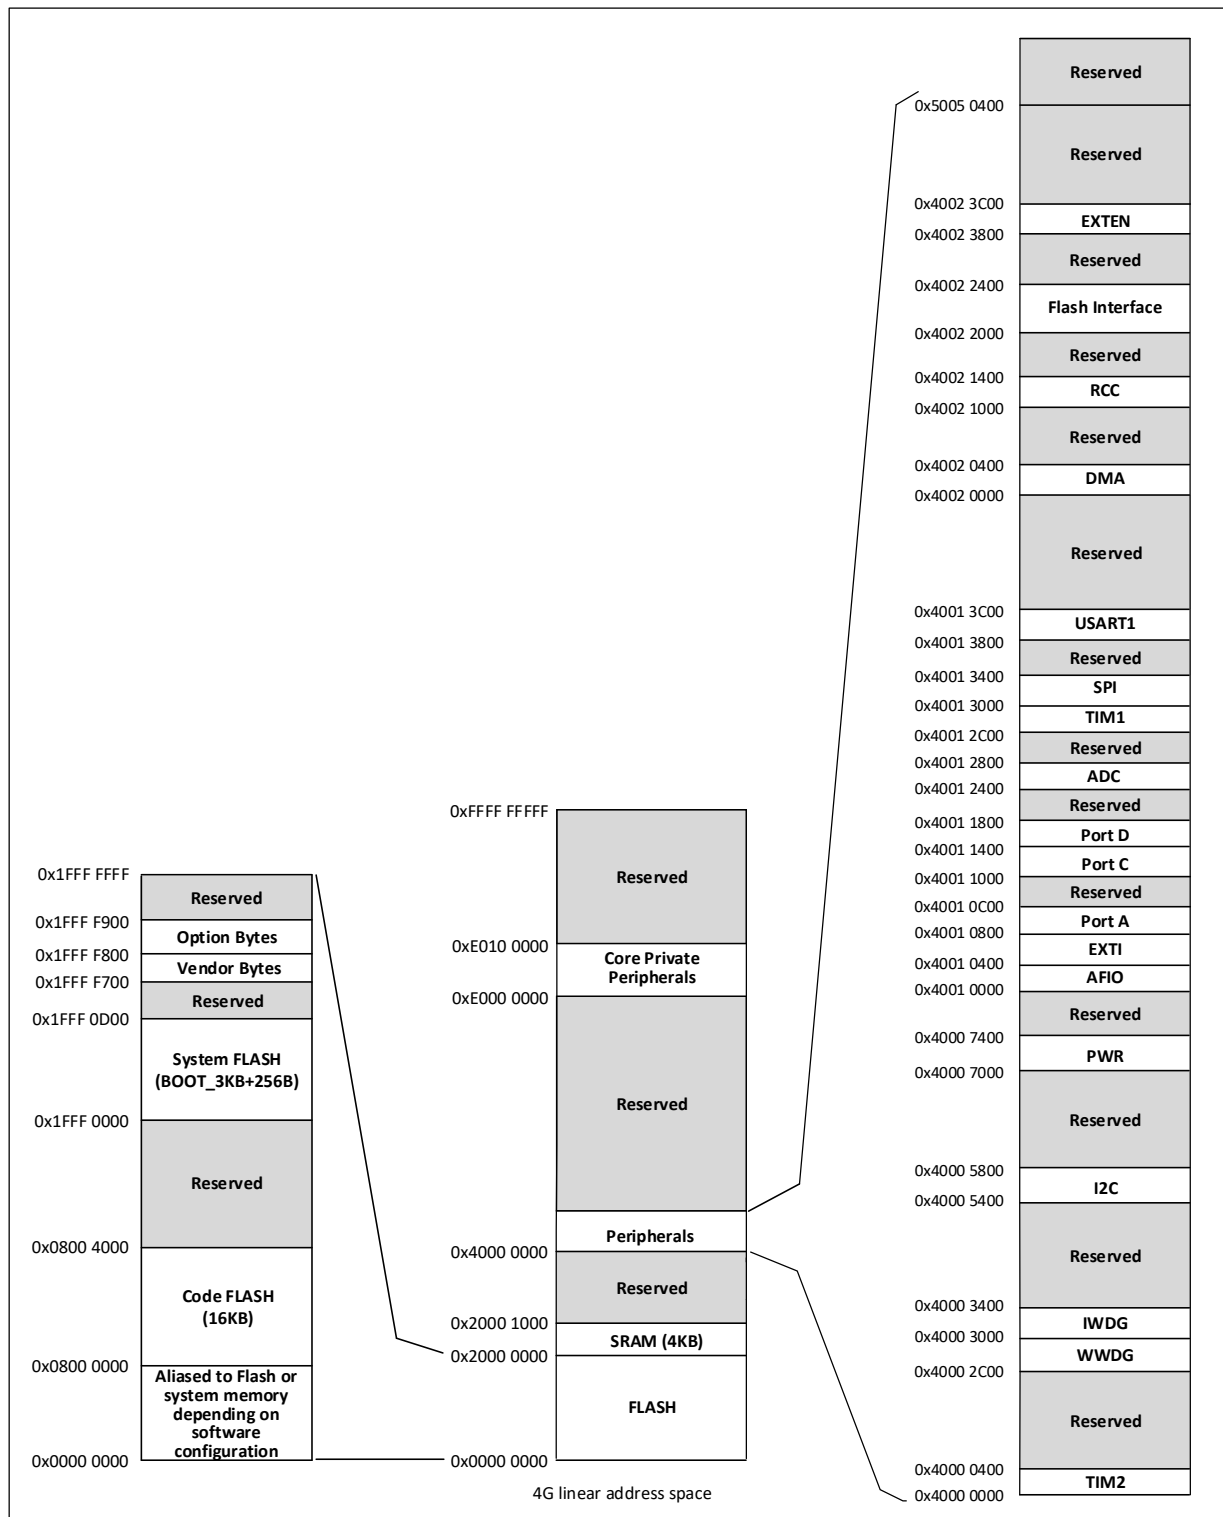

Figure 1-7 CH32V004 Storage image

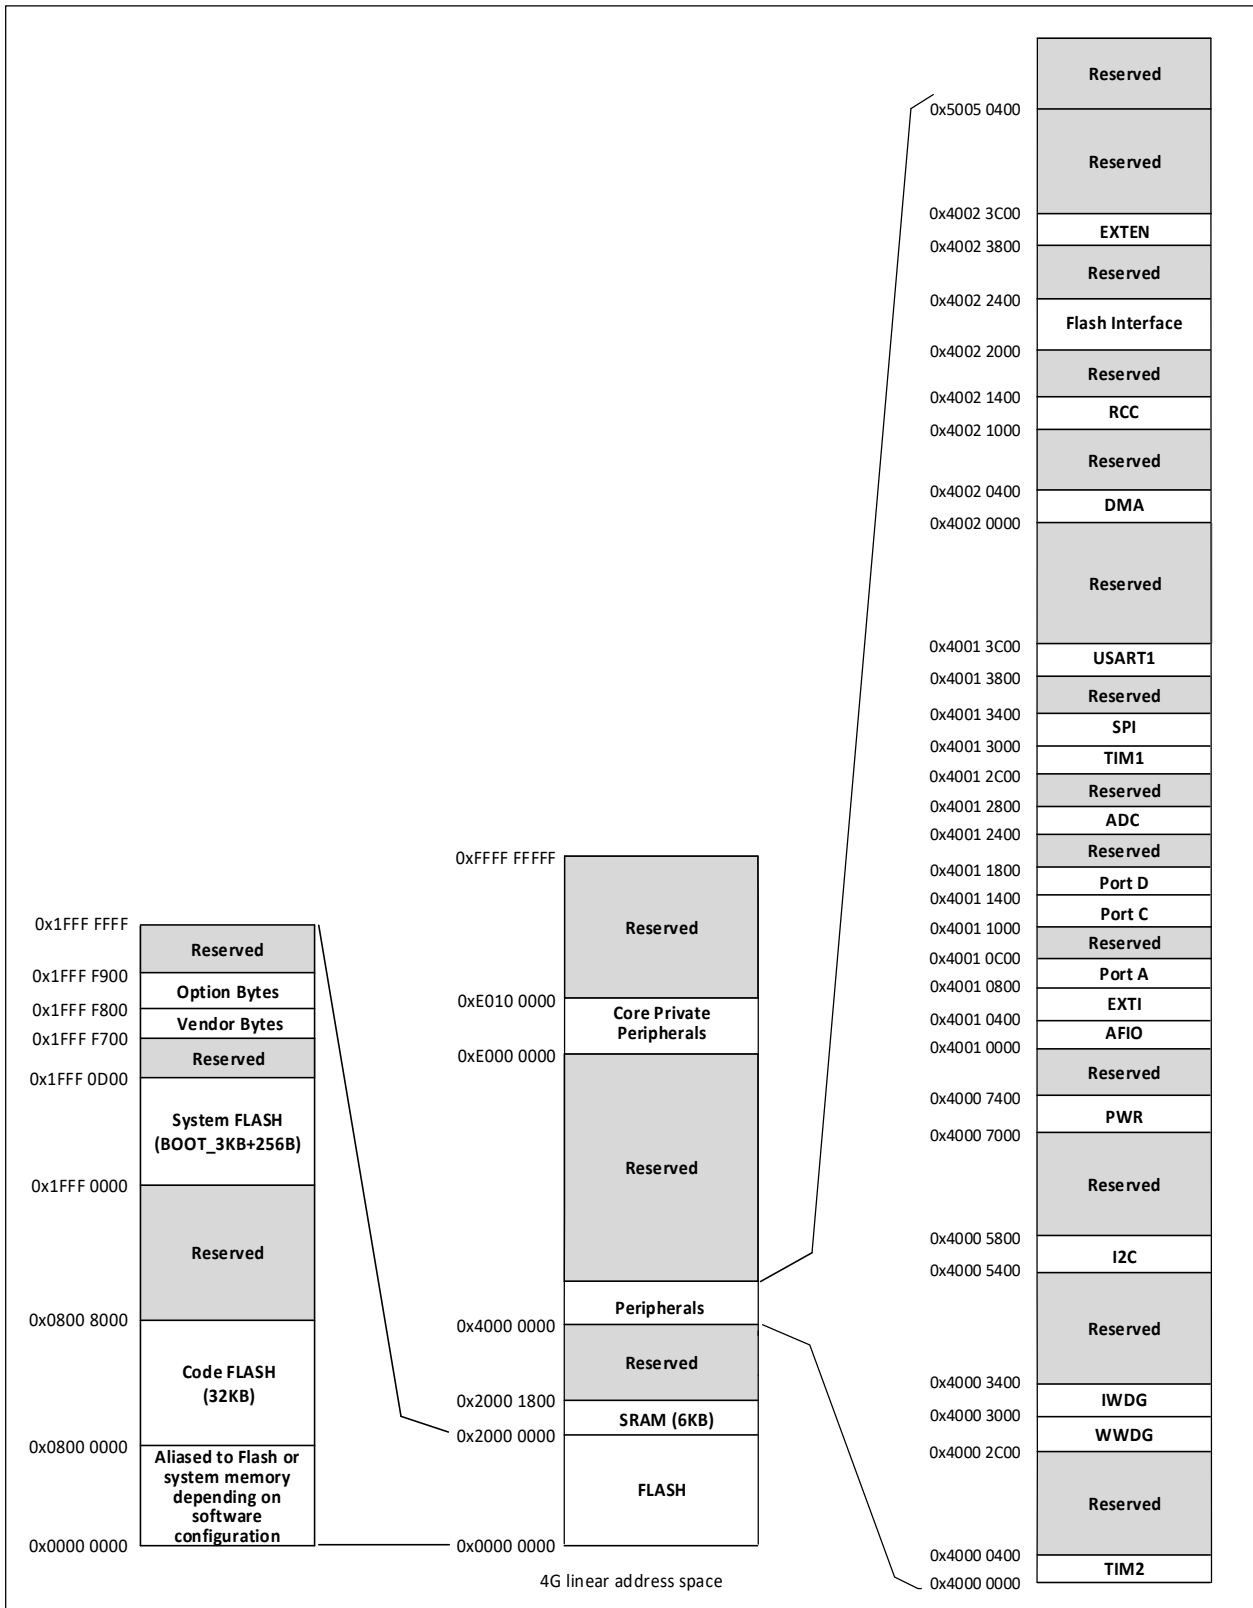

Figure 1-8 CH32V005, CH32V006 Storage image

Note: CH32V005 no TouchKey, TIM3

Figure 1-9 CH32V007, CH32M007 Storage image

### 1.2.1 Memory Allocation

SRAM start address 0x20000000, supports byte, half-word (2-byte), and full-word (4-byte) accesses for storing data, which is lost after power-down.

Program flash memory storage area (Code FLASH), i.e. user area, is used for user's application program and constant data storage.

System storage area (System FLASH), i.e. BOOT area, is used for system boot program storage (Manufacturer's

cured bootloader).

User-defined information storage area for user option byte storage.

*Note: Please refer to the corresponding datasheet for the details of the storage allocation for each model.*

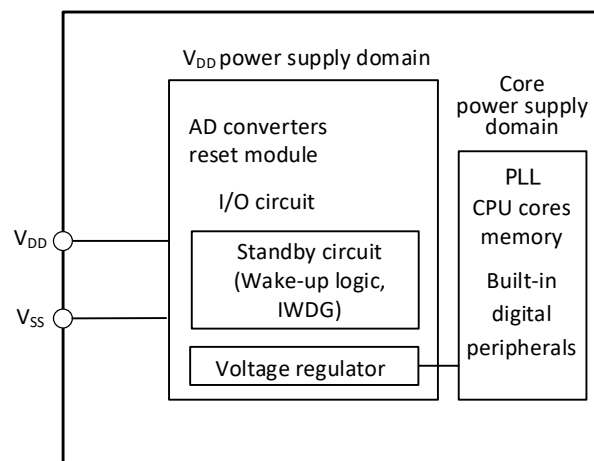

## Chapter 2 Power Control (PWR)

The module descriptions in this chapter apply to the full range of CH32V00X microcontrollers.

### 2.1 Overview

For CH32V002, CH32V004, CH32V005, CH32V006, CH32V007, the operating voltage of the system ranges from 1.9V to 5.5V, and the built-in voltage regulator provides the working power required by the core. The power supply structure is shown in figure 2-1.

Figure 2-1 Block diagram of power supply structure

For CH32M007:

V<sub>HV</sub>: Supplies power to the internal high voltage regulator.

V<sub>CC12V</sub>: Supplies power to the internal gate driver as well as the internal low voltage regulator.

V<sub>DD</sub>: Supplies power to the I/O pins.

## 2.2 Power Management

### 2.2.1 Power-on Reset and Power-down Reset

The power-on reset POR and power-off reset PDR circuits are integrated in the system. When the chip supply voltage V<sub>DD</sub> is lower than the corresponding threshold voltage, the system is reset by the relevant circuits, and there is no need for additional external reset circuits. For the parameters of power-on threshold voltage V<sub>POR</sub> and power-off threshold voltage V<sub>PDR</sub>, please refer to the corresponding data manual.

Figure 2-2 Schematic diagram of the operation of POR and PDR

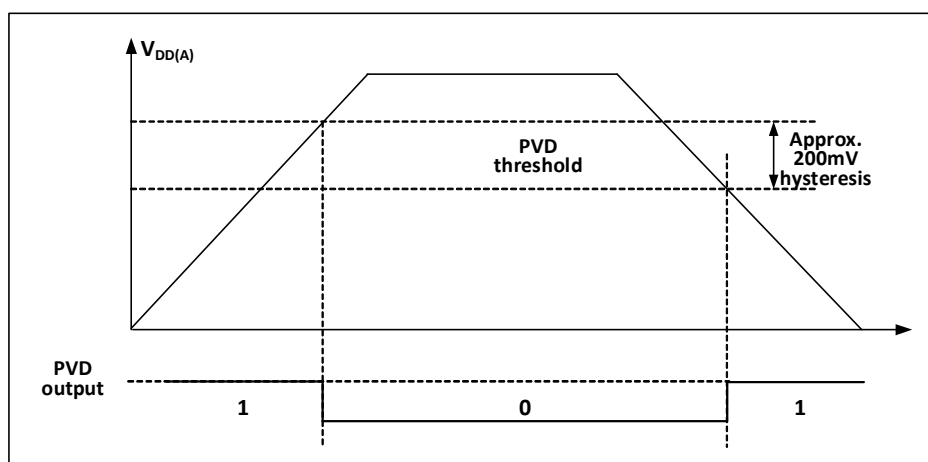

### 2.2.2 Programmable Voltage Detector

The programmable voltage monitor, PVD, is mainly used to monitor the change of the main power supply of the system and compare it with the threshold voltage set by PLS[1:0] of the power control register PWR\_CTLR, and with the external interrupt register (EXTI) setting, it can generate relevant interrupts to notify the system in time for pre-power down operations such as data saving.

The specific configuration is as follows.

- 1) Set the PLS[1:0] field of the PWR\_CTLR register to select the voltage threshold to be monitored.
- 2) Optional interrupt handling. the PVD function internally connects to the rising/falling edge trigger setting of line 8 of the EXTI module, turns on this interrupt (Configures EXTI), and generates a PVD interrupt when  $V_{DD}$  drops below the PVD threshold or rises above the PVD threshold.
- 3) Set the PVDE bit of PWR\_CTLR register to enable the PVD function.
- 4) Read the PVD0 bit of PWR\_CSR status register to obtain the current system main power and PLS[1:0] setting threshold relationship, and perform the corresponding soft processing. When the  $V_{DD}$  voltage is higher than the threshold set by PLS[1:0], PVD0 position 0; when the  $V_{DD}$  voltage is lower than the threshold set by PLS[1:0], PVD0 position 1.

Figure 2-3 Schematic diagram of PVD operation

Note: The function is apply for CH32V002, CH32V005, CH32V006, CH32V007, CH32M007 model chips.

## 2.3 Low-power Modes

After a system reset, the microcontroller is in a normal operating state (Run mode), where system power can be saved by reducing the system main frequency or turning off the unused peripheral clock or reducing the operating peripheral clock. If the system does not need to work, you can set the system to enter low-power mode and let the system jump out of this state by specific events.

Microcontrollers currently offer 2 low-power modes, divided in terms of operating differences between processors, peripherals, voltage regulators, etc.

- Sleep mode: The core stops running and all peripherals (Including core private peripherals) are still running.
- Standby mode: Stop all clocks, wake up and switch the clock to HSI.

Table 2-1 Low-power mode list

| Mode    | Enter  | Wakeup source   | Effect on clock                                 | Voltage regulator |
|---------|--|---|---|-------------------|
| Sleep   | WFI  | Any interrupt   | Core clock OFF,<br>no effect on other<br>clocks | Normal            |
|         | WFE  | Wake-up event   |   |                   |
| Standby | Set SLEEPDEEP<br>to 1<br>Set PDDS to 1<br>WFI or WFE | AWU event<br><i>Note: Any event can also wake<br/>up the system, but the system<br/>does not reset after waking up.</i> | HSE, HSI, PLL<br>and peripheral<br>clock OFF    | Low-power mode    |

Note: SLEEPDEEP bit belongs to core private peripheral control bit, CH32V00X series products refer to PFIC\_SCTLR register.

### 2.3.1 Low-power Configuration Options

- WFI and WFE

WFI: The microcontroller is woken up by an interrupt source with interrupt controller response, and the interrupt service function will be executed first after the system wakes up (Except for microcontroller reset).

WFE: The wakeup event triggers the microcontroller to exit low-power mode. Wake-up events include.

- 1) Configure an external or internal EXTI line to event mode, when no interrupt controller needs to be configured.
- 2) Or configure an interrupt source, equivalent to a WFI wakeup, where the system prioritizes the execution of the interrupt service function.
- 3) Or configure the SLEEPONPEN bit to turn on peripheral interrupt enable, but not interrupt enable in the interrupt controller, and the interrupt pending bit needs to be cleared after the system wakes up.

- SLEEPONEXIT

Enable: After executing the WFI or WFE instruction, the microcontroller ensures that all pending interrupt services are exited and then enters low-power mode.

Not enabled: The microcontroller enters low-power mode immediately after executing the WFI or WFE command.

- SEVONPEND

Enable: All interrupts or wake-up events can wake up the low-power consumption entered by executing WFE.

Not enabled: Only interrupts or wake-up events enabled in the interrupt controller can wake up the low-power consumption entered by executing WFE.

### 2.3.2 Sleep Mode (SLEEP)

In this mode, all I/O pins keep their state in Run mode and all peripheral clocks are normal, so try to turn off useless

peripheral clocks before entering Sleep mode to reduce low-power consumption. This mode takes the shortest time to wake up.

Enter: Configure core register control bit SLEEPDEEP=0, power control register PDDS=0, execute WFI or WFE, optionally SEVONPEND and SLEEPONEXIT.

Exit: Arbitrary interrupt or wakeup event.

### 2.3.3 Standby Mode (STANDBY)

Standby mode is a combination of peripheral clock control mechanisms based on the core's deep Sleep mode (SLEEPDEEP) and allows the voltage regulator to operate at a much lower-power consumption. This mode has the high frequency clock (HSE/HSI/PLL) domain turned off, the SRAM and register contents held, and the I/O pin state held. The system can continue to run after this mode wakes up, and the HSI is called the default system clock.

If flash programming is in progress, the system does not enter Standby mode until access to memory is complete.

Standby mode can work modules: Independent Watchdog (IWDG), Low Frequency Clock (LSI).

Enter: Configure the core register control bit SLEEPDEEP=1, PDDS=1 in the power control register, and execute WFI or WFE, optionally SEVONPEND and SLEEPONEXIT.

Exit: Any external interrupt / event (EXTI signal), external reset signal on RST, IWDG reset, PVD output, AWU automatic wake-up, etc.

### 2.3.4 Auto-wakeup (AWU)

It can wake up automatically without external interruption. By programming the time base, it can be awakened periodically from standby mode.

When you turn on the AWU interrupt function, you need to trigger the rising / falling edge of line 9 of the internal connection to the EXTI module to turn on this interrupt (Configure EXTI).

The optional internal low frequency 128KHz clock oscillator LSI is used as the automatic wake-up count time base.

## 2.4 Register Description

Table 2-2 PWR-related registers list

| Name           | Access address | Description                                  | Reset value |
|----------------|----------------|--|-------------|
| R32_PWR_CTLR   | 0x40007000     | Power Control Register                       | 0x00000408  |
| R32_PWR_CSR    | 0x40007004     | Power Control/Status Register                | 0x00000000  |
| R32_PWR_AWUCSR | 0x40007008     | Auto-wakeup Control/Status Register          | 0x00000000  |

## Chapter 3 Reset and Clock Control (RCC)

*The module described in this chapter is suitable for the full range of CH32V00X microcontrollers.*

According to the division of power supply area and the consideration of peripheral power management in application, the controller provides different reset forms and configurable clock tree structure. This chapter describes the scope of each clock in the system.

### 3.1 Main Features

- Multiple reset forms
- Multiple clock sources, bus clock management
- Built-in external crystal oscillation monitoring and clock security system
- Independent management of each peripheral clock: Reset, on, off
- Support internal clock output

### 3.2 Reset

The controller provides 2 forms of reset: power Reset and system Reset.

#### 3.2.1 Power Reset

When a power Reset occurs, it will reset all registers.

A power Reset is generated when the following event occurs:

- Power-up/power-down reset (POR/PDR)

#### 3.2.2 System Reset

When a system Reset occurs, it will reset the reset flag in addition to the control/status register RCC\_RSTSCKR and all the registers. The source of the reset event is identified by looking at the reset status flag bit in the RCC\_RSTSCKR register.

A system Reset is generated when one of the following events occurs:

- Low signal on NRST pin (External reset)
- Window watchdog count termination (WWDG reset)
- Independent watchdog count termination (IWDG reset)
- Software reset (SW reset)
- Low-power management reset
- ADC reset
- OPCM reset

Window/Independent Watchdog Reset: Generated by the window/independent watchdog peripheral timer count cycle overflow trigger, see its corresponding section for detailed description.

Software reset: The CH32V00X product resets the system via the RSTSYS position 1 of the interrupt configuration register PFIC\_CFGR in the programmable interrupt controller PFIC or the SYSRST position 1 of the configuration register PFIC\_SCTLR to reset the system cabinet, refer to the corresponding chapter for details.

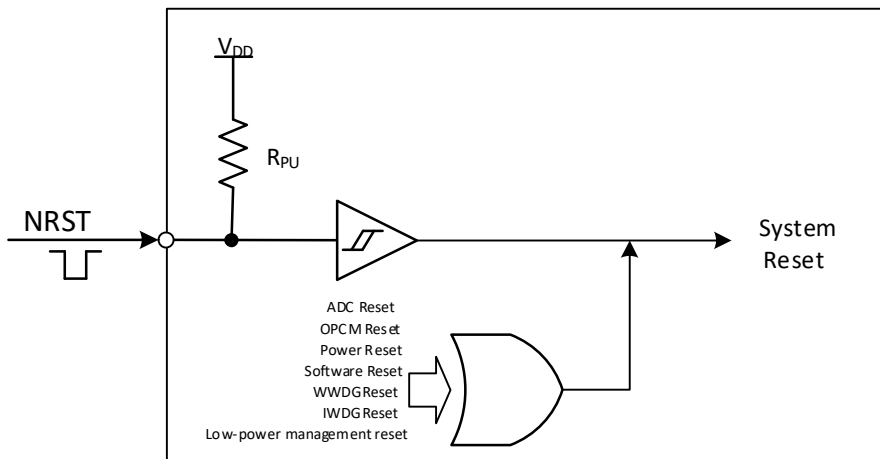

Low Power Management Reset: Standby mode reset will be enabled by setting the STANDBY\_RST position 1 in the user option byte. This will perform a system reset instead of entering standby mode after the process of entering

standby mode is executed.

ADC Reset: With ADC watchdog reset enable on, an ADC reset is generated when the ADC data is greater than the watchdog high threshold or less than the watchdog low threshold.

OPCM Reset: With OPA Reset Enable and CMP Reset Enable turned on, an OPCM reset is generated when the OPA or CMP output goes high.

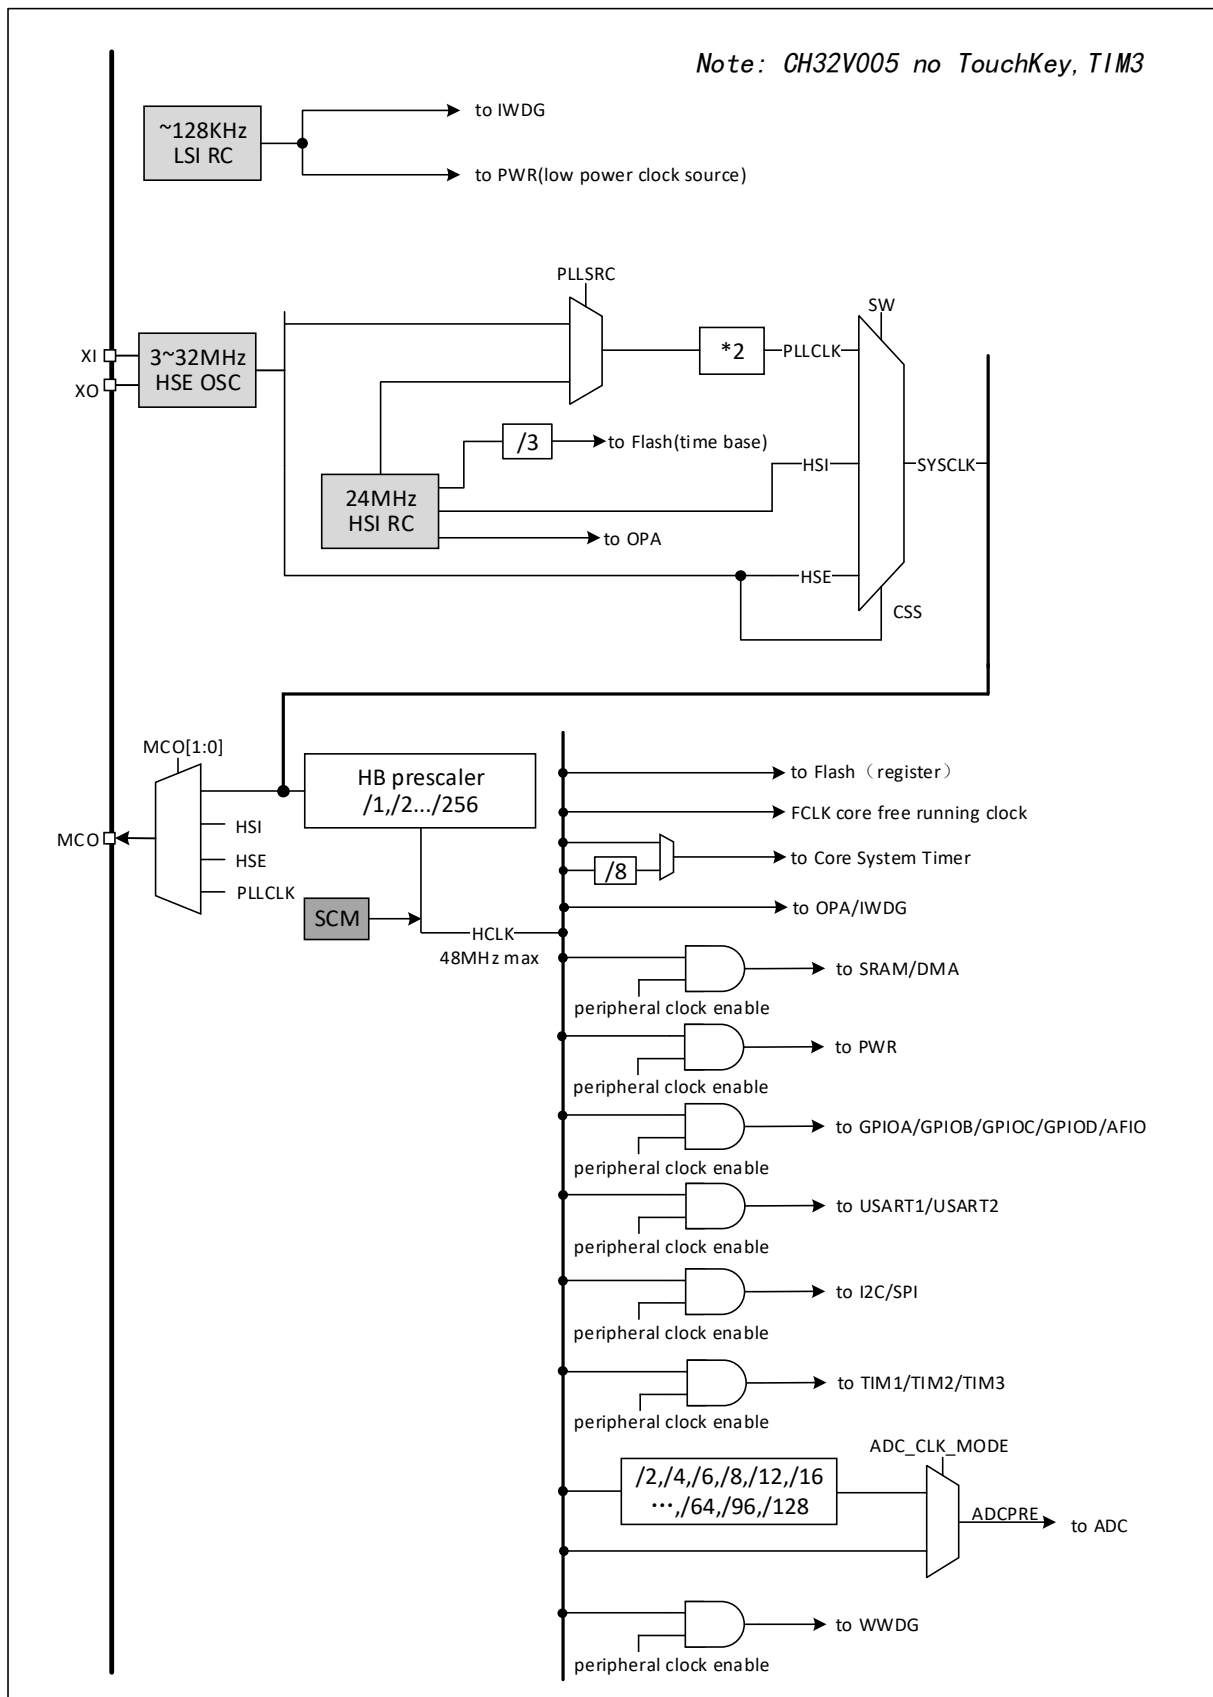

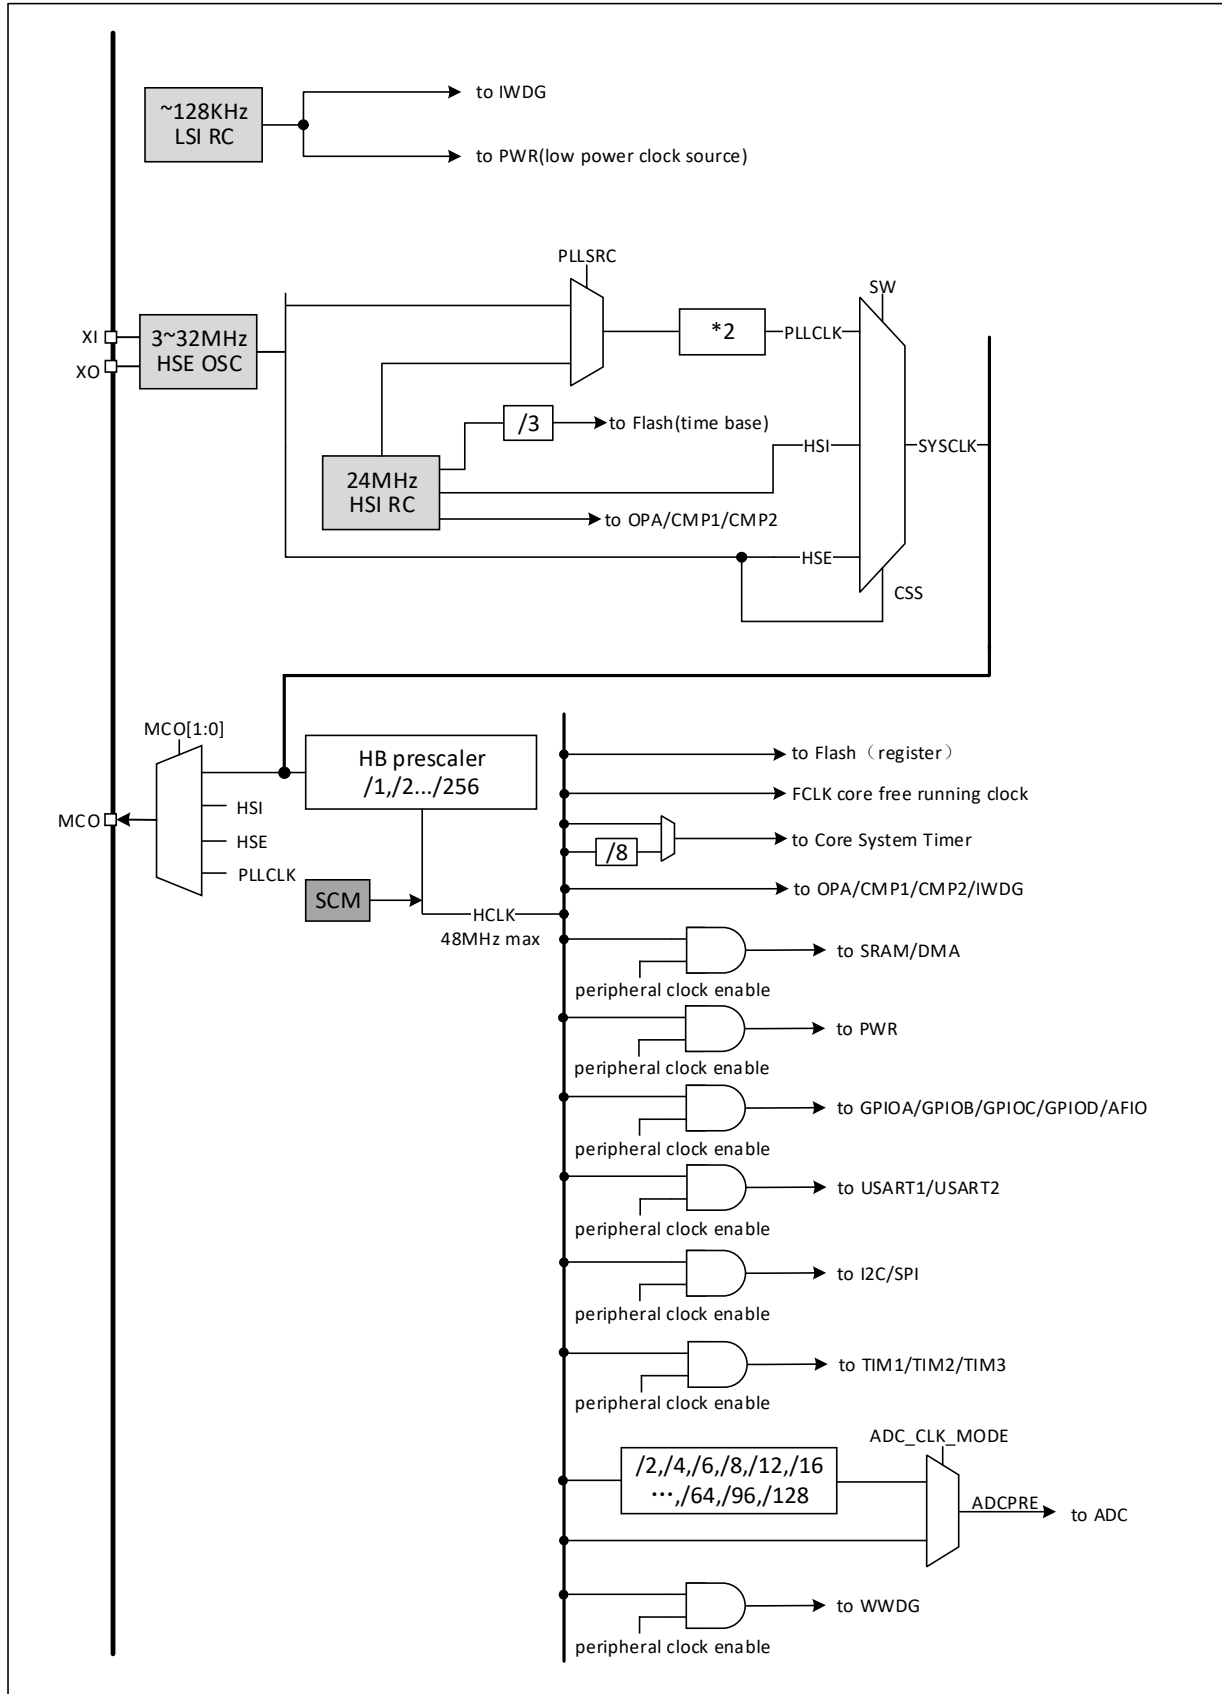

Figure 3-4 CH32V007, CH32M007 clock tree block diagram

### 3.3.2 High-speed Clock (HSI/HSE)

HSI is a high-speed clock signal generated by the system's internal 24MHz RC oscillator. HSI RC oscillator can provide system clock without any external devices. It has a short start-up time. HSI is enabled and disabled by setting the HSION bit in the RCC\_CTLR register, and the HSIRDY bit indicates whether the HSI RC oscillator is stable or not. The system defaults HSION and HSIRDY to 1 (It is recommended not to turn them off). If the HSIRDYIE bit in the RCC\_INTR register is set, the corresponding interrupt will be generated.

- **Factory calibration:** The difference of manufacturing process will cause different RC oscillation frequency for each chip, so HSI calibration is performed for each chip before it is shipped. After system reset, the factory calibration value is loaded into HSICAL[7:0] of the RCC\_CTLR register.
- **User tuning:** Based on different voltages or ambient temperatures, the application can adjust the HSI frequency by using the HSITRIM[4:0] bits in the RCC\_CTLR register.

*Note: If the HSE crystal oscillator fails, the HSI clock is used as a backup clock source (Clock safety system).*

HSE is an external high speed clock signal, including external crystal/ceramic resonator generation or external high speed clock feed.

- **External crystal / ceramic resonator (HSE crystal):** external oscillator provides a more accurate clock source for the system. For further information, please refer to the electrical characteristics section of the data manual. The HSE crystal can be turned on and off by setting the HSEON bit in the RCC\_CTLR register, and the HSERDY bit indicates whether the HSE crystal oscillation is stable or not, and the hardware sends the clock into the system after HSERDY position 1. If the HSERDYIE bit of the RCC\_INTR register is set, the corresponding interrupt will be generated.

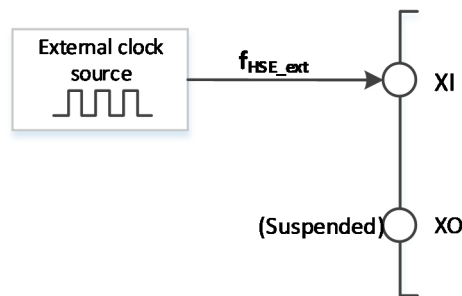

Figure 3-5 High-speed external crystal circuit

*Note: The load capacitance should be as close to the oscillator pin as possible, and the capacity value should be selected according to the parameters of the crystal manufacturer.*

- **External high-speed clock source (HSE bypass):** this mode feeds the clock source directly from the outside to the XI pin, and the XO pin is suspended. The application needs to set the HSEBYP bit when the HSEON bit is 0, turn on the HSE bypass function, and then set the HSEON bit.

Figure 3-6 High-speed clock source circuit

### 3.3.3 Low-speed Clock (LSI)

LSI is a low-speed clock signal generated by a RC oscillator of about 128KHz in the system. It can keep running in standby mode, providing a clock reference for independent watchdogs and wake-up units. For further information, please refer to the electrical characteristics section of the data manual. LSI can be turned on and off by setting the LSION bit in the RCC\_RSTSCKR register, and then check whether the LSIRC oscillation is stable by querying the LSIRDY bit, and the hardware sends the clock in after LSIRDY position 1. If the LSIRDYIE bit of the RCC\_INTR register is set, the corresponding interrupt will be generated.

### 3.3.4 PLL Clock (PLLCLK)

The internal PLL clock can be selected from 2 clock sources by configuring the PLLSRC bit in the RCC\_CFGR0 register, these settings must be done before the PLL is turned on, once the PLL is powered up these parameters cannot be altered. Setting the PLLON bit in the RCC\_CTLR register is activated and deactivated, the PLLRDY bit indicates whether the PLL clock is stable or not, and the hardware sends the clock into the system only after PLL position 1. If the PLLRDYIE bit in the RCC\_INTR register is set, the corresponding interrupt is generated.

PLL clock source:

- HSI clock
- HSE Clock

### 3.3.5 Bus/Peripheral Clock

#### 3.3.5.1 System Clock (SYSCLK)

By configuring the RCC\_CFGR0 register SW [1:0] bit to configure the system clock source, SWS [1:0] indicates the current system clock source.

- HSI as system clock
- HSE as system clock
- PLL as system clock

After a controller reset, the default HSI clock is selected as the system clock source. Switching between clock sources must occur only when the target clock source is ready.

#### 3.3.5.2 HB Bus Peripheral Clock (HCLK)

You can configure the clock of the HB bus by configuring the HPRE [3:0] bit of the RCC\_CFGR0 register. The bus clock determines that the peripheral interface mounted below it accesses the clock reference. The application can reduce the power consumption of some peripherals by adjusting different values.

Through each bit in the RCC\_PB1PRSTR and RCC\_PB2PRSTR registers, different peripheral modules can be reset and restored to the initial state.

The communication clock interface of different peripheral modules can be turned on or off separately through each bit in the RCC\_HBPCENR, RCC\_PB1PCENR and RCC\_PB2PCENR registers. When using a peripheral, you first need to turn on its clock enable bit before you can access its register.

### 3.3.5.3 Independent Watchdog Clock

If the independent watchdog has been started by the hardware configuration or software, the LSI oscillator will be forced to open and cannot be turned off. After the LSI oscillator is stabilized, the clock is supplied to the IWDG.

### 3.3.5.4 Microcontroller Clock Output (MCO)

The microcontroller allows clock signals to be output to MCO pins. The multiplexing push-pull output mode is configured in the corresponding GPIO port register. by configuring the RCC\_CFGR0 register MCO [2:0] bit, the following 4 clock signals can be selected as MCO clock output:

- System clock (SYSCLK) output
- HSI clock output
- HSE clock output
- PLL clock output

### 3.3.6 Clock Security System (CSS)

The clock security system is a running protection mechanism of the controller, which can switch to the HSI clock in the case of HSE clock transmission failure, and generate interrupt notification, allowing application software to complete the rescue operation.

Activate the clock security system by setting CSSON position 1 of the RCC\_CTLR register. At this point, the clock monitor will be enabled after the HSE oscillator startup (HSERDY=1) delay and turned off after the HSE clock is turned off. Once the HSE clock fails during the operation of the system, the HSE oscillator will be turned off, the clock failure event will be sent to the brake input of the advanced timer (TIM1), and the clock security interrupt will be generated, CSSF position 1, and the application will enter the NMI unshielded interrupt. By setting the CSSC bit, the CSSF bit flag can be cleared and the NMI interrupt suspension bit can be revoked.

If the current HSE is the system clock, or the current HSE is the PLL input clock and the PLL is the system clock, the clock security system will automatically switch the system clock to the HSI oscillator and turn off the HSE oscillator and PLL in the event of a HSE failure.

### 3.3.7 System Clock Monitoring System (SCM)

The system clock monitoring system is a system clock monitoring mechanism of the controller. After the SYSCM\_EN bit is turned on, if the system clock failure event occurs, the brake signal will be generated to the advanced timer TIM1, and the system clock failure flag (SYSCLK\_FAILIF) will be set; if the SYSCLK\_FAILIE bit is enabled in advance, it will enter the system clock failure interrupt.

## 3.4 Register Description

Table 3-1 RCC-related registers list

| Name          | Access address | Description                  | Reset value |
|---------------|----------------|------------------------------|-------------|
| R32_RCC_CTLR  | 0x40021000     | Clock Control Register       | 0x0050XX83  |
| R32_RCC_CFGR0 | 0x40021004     | Clock Configuration Register | 0x00000020  |
| R32_RCC_INTR  | 0x40021008     | Clock Interrupt Register     | 0x00000000  |

|                  |            |                                      |            |
|------------------|------------|--------------------------------------|------------|
| R32_RCC_PB2PRSTR | 0x4002100C | PB2 Peripheral Reset Register        | 0x00000000 |
| R32_RCC_PB1PRSTR | 0x40021010 | PB1 Peripheral Reset Register        | 0x00000000 |
| R32_RCC_HBPCENR  | 0x40021014 | HB Peripheral Clock Enable Register  | 0x00000004 |
| R32_RCC_PB2PCENR | 0x40021018 | PB2 Peripheral Clock Enable Register | 0x00000000 |
| R32_RCC_PB1PCENR | 0x4002101C | PB1 Peripheral Clock Enable Register | 0x00000000 |
| R32_RCC_RSTSCKR  | 0x40021024 | Control/Status register              | 0x08000000 |

## Chapter 4 Independent Watchdog (IWDG)

*The module described in this chapter is suitable for the full range of CH32V00X microcontrollers.*

The system is equipped with an independent watchdog (IWDG) to detect software failures caused by logic errors and external environment interference. The IWDG clock source comes from LSI and can be run independently of the main program, so it is suitable for situations with low precision requirements.

### 4.1 Main Features

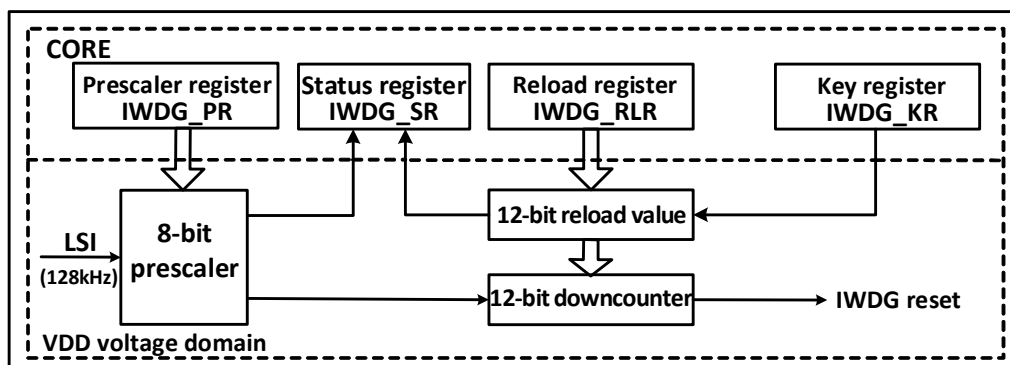

- 12-bit self-subtracting counter
- Clock source LSI divider, can run in low-power mode
- Reset condition: Counter value is reduced to 0

### 4.2 Function Description

#### 4.2.1 Principle and Application

Independent watchdog clock source LSI clock, its function can still work in standby mode. When the watchdog counter decrements itself to 0, a system reset will be generated, so the timeout is (Reload value + 1) clock.

Figure 4-1 Block diagram of the structure of the independent watchdog

- Enable independent watchdog

After the system is reset, the watchdog is off, and the watchdog is turned on by writing 0xCCCC to the IWDG\_CTLR register. After that, it can no longer be turned off unless a reset occurs.

If the hardware independent watchdog enable bit (IWDG\_SW) is turned on in the user option byte, the IWDG will be permanently turned on after the microcontroller resets.

- Watchdog configuration

Inside the watchdog is a 12-bit counter running progressively. When the value of the counter is reduced to 0, a system reset will occur. To enable the IWDG function, you need to perform the following actions:

- 1) Counting time base: IWDG clock source LSI, through the IWDG\_PSCR register to set the LSI frequency division value clock as the IWDG counting time base. Operation method: first write 0x5555 to the IWDG\_CTLR register, and then modify the frequency division value in the IWDG\_PSCR register. The PVU bit in the IWDG\_STATR register indicates the update status of the frequency division value, and the frequency division value can only be modified and read out when the update is completed.
- 2) Reload value: used to update the current value of the counter in the independent watchdog, and the counter is

decremented by this value. Method of operation: first write 0x5555 to the IWDG\_CTLR register, then modify the IWDG\_RLDR register to set the target reload value. The RVU bit in the IWDG\_STATR register indicates the update status of the reload value, and the IWDG\_RLDR register can be modified and read out only after the update is completed.

- 3) Watchdog enable: write 0xCCCC to the IWDG\_CTLR register to turn on the watchdog function.
- 4) Feed the dog: that is, before the watchdog counter decreases to 0, refresh the current counter value to prevent system reset. Write 0xAAAA to the IWDG\_CTLR register and have the hardware update the IWDG\_RLDR register value to the watchdog counter. This action needs to be performed regularly after the watchdog function is turned on, otherwise the watchdog reset action will occur.

### 4.2.2 Debug Mode

When the system enters debug mode, the IWDG counter can be configured by the debug module register to continue to work or stop.

## 4.3 Register Description

Table 4-1 IWDG-related registers list

| Name           | Access address | Description           | Reset value |

|---|-----|----|---|---|
|   |     |    | <p>1: Reload value update in progress;<br/>                 0: Reload update ends (up to 5 LSI cycles).<br/> <i>Note: The reload value register IWDG_RLDR can be read and written only after the RVU bit has been cleared.</i></p>  |   |
| 0 | PVU | RO | <p>Clock frequency division coefficient updates flag bits. Hardware setting or clearing 0.<br/>                 1: Clock division value update is in progress;<br/>                 0: Clock division value update ends (Up to 5 LSI cycles).<br/> <i>Note: The frequency division factor register IWDG_PSCR can be read and written only after the PVU bit has been cleared.</i></p> | 0 |

*Note: After the pre-division or reinstallation value is updated, you do not have to wait for RVU or PVU to reset, you can continue to execute the following code. (This write operation continues to be completed even in low power mode)*

## Chapter 5 Window Watchdog (WWDG)

*The module described in this chapter is suitable for the full range of CH32V00X microcontrollers.*

The window watchdog is generally used to monitor the software failures of the system, such as external interference, unforeseen logic errors and so on. It needs to refresh the counter (Feed the dog) within a specific window time (With upper and lower limits), otherwise the watchdog circuit will produce a system reset earlier or later than this window time.

### 5.1 Main Features

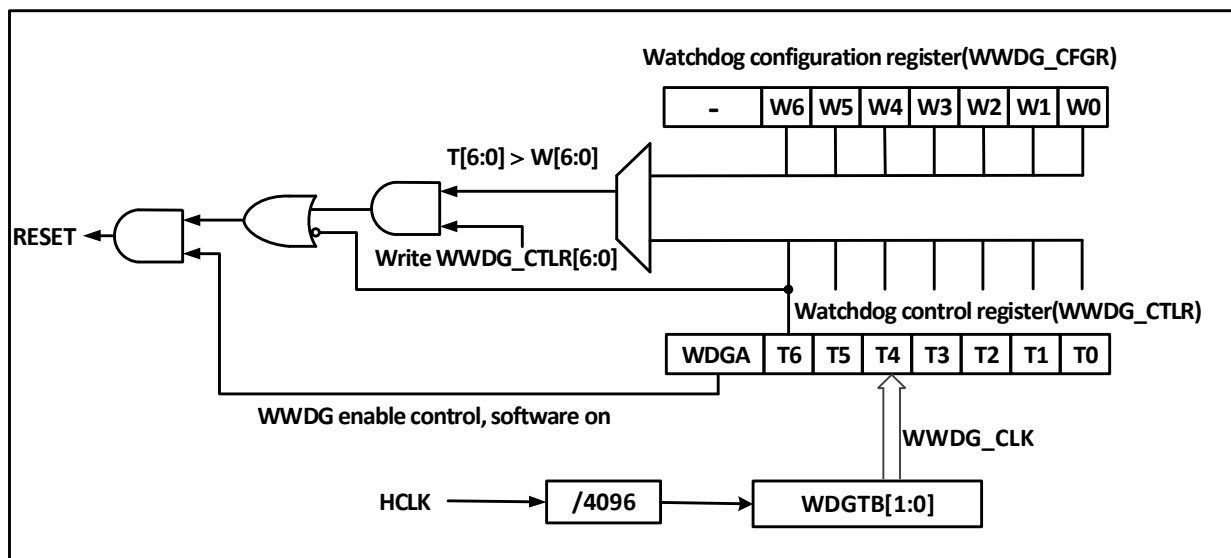

- Programmable 7-bit self-subtractive counter
- Double conditional reset: the current counter value is less than 0x40, or the counter value is reloaded outside the window time
- Wake up advance notice function (EWI), used to feed the dog in time to prevent system reset

### 5.2 Function Description

#### 5.2.1 Principle and Application

The window watchdog runs based on a 7-bit decrement counter, which is mounted on the HB bus to count the frequency division of the time-based WWDG \_ CLK source (HCLK/4096) clock, and the frequency division factor is set in the WDG TB [1:0] field in the configuration register WWDG \_ CFGR. The decrement counter is in a state of free operation, regardless of whether the watchdog function is turned on or not, the counter has been cyclically decreasing counting. As shown in figure 5-1, the internal structure block diagram of the window watchdog.

Figure 5-1 Block diagram of Window Watchdog structure

- Enable window watchdog

After the system is reset, the watchdog is off, the WDGA bit of the WWDG \_ CTLR register is set to turn on the watchdog, and then it can no longer be turned off unless a reset occurs.

*Note: You can turn off the clock source of the WWDG by setting the RCC\_PBIPCENR register, pause the WWDG \_ CLK count, stop the watchdog function indirectly, or reset the WWDG module by setting the RCC\_PBIPRSTR register, which is equivalent to a reset.*

- Watchdog configuration

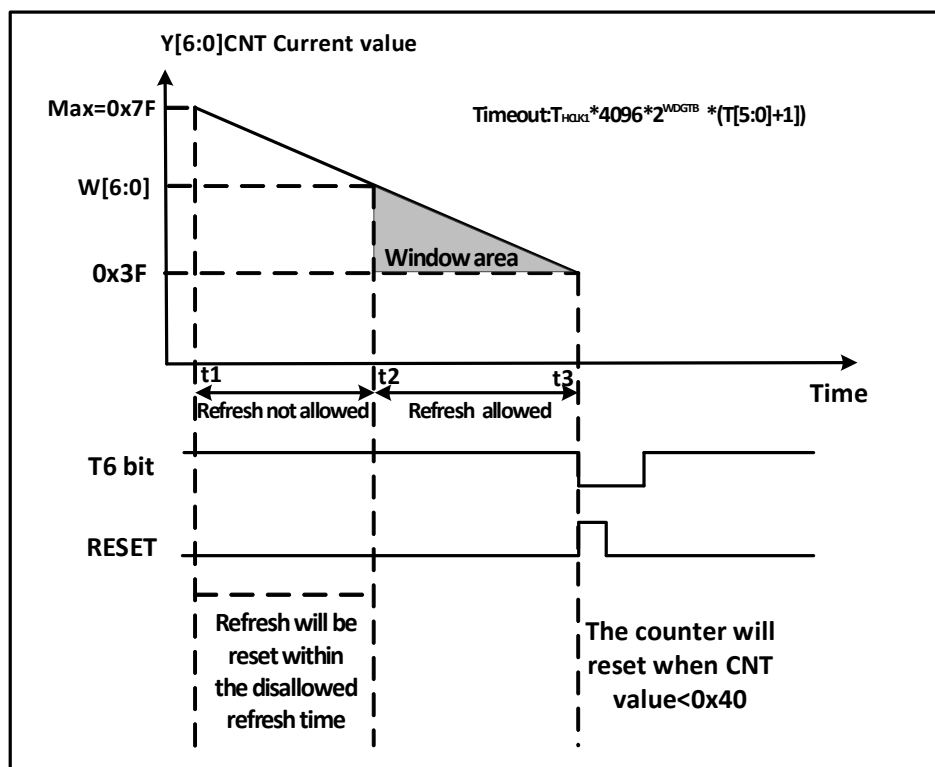

Inside the watchdog is a 7-bit counter running in a continuous cycle, which supports read and write access. To use the watchdog reset function, you need to perform the following actions:

- 1) Count time base: through the WDG TB [1:0] bit field of the WWDG\_CFGR register, be careful to turn on the WWDG module clock of the RCC unit.
- 2) Window counter: sets the W [6:0] bit field of the WWDG\_CFGR register. This counter is used by hardware to compare with the current counter. The value is configured by the user's software and will not be changed. As the upper limit of the window time.
- 3) Watchdog enable: WWDG\_CTLR register WDGA bit software set 1, turn on watchdog function, you can reset the system.
- 4) Feed the dog: that is, refresh the current counter value and configure the T [6:0] bit field of the WWDG\_CTLR register. This action needs to be performed within the periodic window time after the watchdog function is turned on, otherwise the watchdog reset action will occur.

- Feed the dog window time

As shown in figure 5-2, the grey area is the monitoring window area of the window watchdog, and its upper limit time  $t_2$  corresponds to the time point at which the counter value reaches the window value W[6:0], and its lower limit time  $t_3$  corresponds to the time point at which the counter value reaches 0x3F. In this area,  $t_2 < t < t_3$  can carry out dog feeding operation (write T[6:0]) to refresh the value of the current counter.

Figure 5-2 Counting mode of Window Watchdog

- Watchdog reset

- 1) When the dog is not fed in time, resulting in the value of the T[6:0] counter from 0x40 to 0x3F, a "window watchdog reset" will appear, resulting in a system reset. That is, if the T6-bit is detected as 0 by the hardware, a system reset will occur.

Note: The application program can write T6-bit to 0 through software to realize system reset and equivalent software reset function.

2) When the counter refresh action is performed within the dog feeding time, that is, the write T [6:0] bit field is operated within the  $t1 \leq t \leq t2$  time, a "window watchdog reset" will appear, resulting in a system reset.

- Wakeup in advance

To prevent the system from resetting due to failure to refresh the counter in time, the watchdog module provides early wake-up interrupt (EWI) notification. When the counter is reduced to 0x40, an early wake-up signal is generated, and the EWIF flag is set to 1. If the EWI bit is set, the window watchdog will be triggered to interrupt at the same time. At this point, there is a counter clock cycle (Self-reduced to 0x3F) from the hardware reset, during which the application can immediately feed the dog.

## 5.2.2 Debug Mode

When the system enters debug mode, the WWDG counter can be configured by the debug module register to continue to work or stop.

## 5.3 Register Description

| [15:1] | Reserved | WO     | Reserved  | 0           |
| 0      | EWIF     | RW0    | Wake up the interrupt flag bit in advance.<br>When the counter reaches 0x40, this bit is set by hardware and must be cleared by software. The user setting is invalid. Even if the EWI is not set, it will be set as usual when the event occurs. | 0           |

## Chapter 6 Interrupt and Events (PFIC)

*The module described in this chapter is suitable for the full range of CH32V00X microcontrollers.*

The CH32V00X series has a built-in programmable fast interrupt controller (PFIC- Programmable Fast Interrupt Controller) that supports up to 255 interrupt vectors. The current system manages 25 peripheral interrupt channels and 4 kernel interrupt channels, and the rest are retained.

### 6.1 Main features

#### 6.1.1 PFIC Controller

- 25 peripheral interrupts, each interrupt request has independent trigger and mask control bits, with dedicated status bits
- Programmable multi-level interrupt nesting, maximum nesting depth 2 levels, hardware stack depth 2 levels
- Fast interrupt entry and exit mechanism, hardware automatic stacking and recovery
- Vector Table Free (VTF) interrupt response mechanism, 2-channel programmable direct access to interrupt vector addresses

### 6.2 System Timer

- CH32V00X Series

The core comes with a 32-bit add counter (SysTick) that supports HCLK or HCLK/8 as a time base with high priority and can be used as a time reference after calibration.

### 6.3 Vector Table of Interrupts and Exceptions

Table 6-1 CH32V00X series vector table

| No.  | Priority | Type         | Name      | Description                               | Entrance address          |
|------|----------|--------------|-----------|---|---------------------------|
| 0    | -        | -            | -         | -   | 0x00000000                |

## 6.4 External Interrupt and Event Controller (EXTI)

### 6.4.1 Overview

Figure 6-1 External interrupt (EXTI) interface block diagram

As can be seen from figure 6-1, the trigger source of the external interrupt can be either the software interrupt (SWIEVR) or the actual external interrupt channel, and the signal of the external interrupt channel will first be screened by the edge detection circuit. As long as one of the software interrupts or external interrupt signals is generated, it will be output to both event enabling and interrupt enabling circuits through the OR gate circuit in the diagram. As long as an interrupt is enabled or an event is enabled, an interrupt or event will occur. The six registers of EXTI are accessed by the processor through the HB interface.

### 6.4.2 Wake-up Event

The system can wake up sleep patterns caused by WFE instructions through wake-up events. Wake-up events are generated through the following two configurations:

- Enable an interrupt in the register of the peripheral, but not in the PFIC of the core, and enable the SEVONPEND bit in the core. Reflected in EXTI, it enables EXTI interrupts, but does not enable EXTI interrupts in PFIC, while enabling SEVONPEND bits. When CPU wakes up from WFE, the interrupt flag bit and PFIC hang bit of EXTI need to be cleared.
- Enable an EXTI channel to be an event channel, and the CPU does not need to clear the interrupt flag bit and the PFIC hang bit after waking up from the WFE.

### 6.4.3 Description

The use of external interrupt needs to configure the corresponding external interrupt channel, that is, select the

appropriate trigger edge to enable the corresponding interrupt. When a set trigger edge appears on the external interrupt channel, an interrupt request will be generated and the corresponding interrupt flag bit will be set. Write 1 to the flag bit to clear it.

Use external hardware interrupt steps:

- 1) Configure GPIO operation
- 2) Configure the interrupt enable level (EXTI\_INTENR) of the corresponding external interrupt channel
- 3) Configure trigger edge (EXTI\_RTENR or EXTI\_FTENR), select rising edge trigger, falling edge trigger, or double edge trigger
- 4) Configure EXTI interrupts in the PFIC of the core to ensure that they respond correctly.

Use external hardware steps:

- 1) Configure GPIO operation
- 2) Configure the event enable level (EXTI\_EVENTR) of the corresponding external interrupt channel
- 3) Configure trigger edge (EXTI\_RTENR or EXTI\_FTENR), select rising edge trigger, falling edge trigger, or double edge trigger.

Use software interrupt/event steps:

- 1) Enable external interrupts (EXTI\_INTENR) or external events (EXTI\_EVENTR)
- 2) If you use the interrupt service function, you need to set the EXTI interrupt in the PFIC of the core
- 3) Set software interrupt trigger (EXTI\_SWIEVR), that is, an interrupt will occur.

## 6.4.4 External Event Mapping

Table 6-2 EXTI Interrupt Mapping

| External interrupt/<br>Event lines | Mapping Event Description   |
|------------------------------------|---|
| EXTI0~EXTI7                        | Px0~Px7 (x=A/B/C/D), Any IO port can enable external interrupt/event function, which is configured by the AFIO_EXTICR register. |
| EXTI8                              | PVD event: voltage monitoring threshold exceeded.   |
| EXTI9                              | Automatic wake-up event.  |

## 6.5 Register Description

### 6.5.1 EXTI Registers

Table 6-3 EXTI-related registers list

| Name            | Access address | Description                          | Reset value |
|-----------------|----------------|--------------------------------------|-------------|
| R32_EXTI_INTENR | 0x40010400     | Interrupt enable register            | 0x00000000  |
| R32_EXTI_EVENTR | 0x40010404     | Event enable register                | 0x00000000  |
| R32_EXTI_RTENR  | 0x40010408     | Rising edge trigger enable register  | 0x00000000  |
| R32_EXTI_FTENR  | 0x4001040C     | Falling edge trigger enable register | 0x00000000  |
| R32_EXTI_SWIEVR | 0x40010410     | Soft interrupt event register        | 0x00000000  |
| R32_EXTI_INTFR  | 0x40010414     | Interrupt flag register              | 0x00000XXX  |

### 6.5.1.1 Interrupt Enable Register (EXTI\_INTENR)

Offset address: 0x00

| Bit     | Name     | Access | Description  | Reset value |
|---------|----------|--------|--|-------------|
| [31:10] | Reserved | RO     | Reserved   | 0           |
| [9:0]   | MRx      | RW     | The interrupt request signal of the external interrupt channel x is enabled.<br>1: Enable interrupts on this channel;<br>0: Mask interrupts on this channel. | 0           |

### 6.5.1.2 Event Enable Register (EXTI\_EVENR)

Offset address: 0x04

| Bit     | Name     | Access | Description  | Reset value |
|---------|----------|--------|--|-------------|
| [31:10] | Reserved | RO     | Reserved   | 0           |
| [9:0]   | MRx      | RW     | The event request signal of the external interrupt channel x is enabled.<br>1: Enable interrupts on this channel;<br>0: Mask interrupts on this channel. | 0           |

### 6.5.1.3 Rising Edge Trigger Enable Register (EXTI\_RTENR)

Offset address: 0x08

| Bit     | Name     | Access | Description   | Reset value |
|---------|----------|--------|---|-------------|
| [31:10] | Reserved | RO     | Reserved  | 0           |
| [9:0]   | TRx      | RW     | Enable the rising edge trigger of the external interrupt channel x.<br>1: Enable rising edge trigger of this channel; | 0           |

|  |  |  |   |  |
|--|--|--|---|--|
|  |  |  | 0: Disable rising edge trigger of this channel. |  |
|--|--|--|---|--|

**6.5.1.4 Falling Edge Trigger Enable Register (EXTI\_FTENR)**

Offset address: 0x0C

|          |    |    |    |    |    |     |     |     |     |     |     |     |     |     |     |
|----------|----|----|----|----|----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

Note: 1. The default value for the PFIC\_ISR1 register is 0xC, that is, NMI and exceptions are always enabled by default.

2. NMI and EXC support interrupting pending cleanup and setting operations, but not interrupting enable cleanup and setting operations.

| 5      | SETEVENT    | WO | Set the event, wake up the WFE situation.  | 0 |
| 4      | SEVONPEND   | RW | When an event or interrupt hang state occurs, the system can be woken up from after the WFE instruction, or if the WFE instruction has not been executed, the system will be woken up immediately after the next execution of the instruction.<br>1: Enabled events and all interrupts (including unopened interrupts) can wake up the system<br>0: Only enabled events and enabled interrupts can wake up the system. | 0 |
| 3      | WFIOWFE     | RW | Execute the WFI instruction as if it were WFE.<br>1: Use the subsequent WFI instruction as the WFE instruction<br>0: No effect.  | 0 |
| 2      | SLEEPDEEP   | RW | Control the low power mode of the system.<br>1: deepsleep;                   0: sleep.   | 0 |
| 1      | SLEEPONEXIT | RW | Control the state of the system after leaving the interrupt service program.<br>1: The system enters low-power mode<br>0: The system enters the main program.  | 0 |
| 0      | Reserved    | RO | Reserved   | 0 |

### 6.5.3 Dedicated CSR Registers

Some Control and Status Registers (CSR) are defined in the RISC-V architecture to configure or identify or record the running status. CSR registers are internal registers within the kernel and use a dedicated 12-bit address space. In addition to the standard registers defined in the RISC-V privileged architecture document, the CH32V00X chip also adds some custom registers that need to be accessed by csr instructions.

*Note: Such registers marked with the "MRW, MRO, MRWI" attribute need to be accessed by the system in machine mode.*

#### 6.5.3.1 Interrupt System Control Register (INTSYSCR)

CSR address: 0x804

|  |         |          |
|--|---------|----------|
|  | T<br>EN | TKE<br>N |
|--|---------|----------|

| Bit    | Name     | Access | Description  | Reset value |
|--------|----------|--------|--|-------------|
| [31:2] | Reserved | MRO    | Reserved   | 0           |
| 1      | INESTEN  | MRW    | Interrupt nesting enable.<br>1: Interrupt nesting function is enabled.<br>0: Interrupt nesting function is disabled. | 0           |
| 0      | HWSTKEN  | MRW    | Hardware stack enable.<br>1: Hardware stacking function is enabled.<br>0: Hardware stacking function is disabled.    | 0           |

### 6.5.3.2 Exception Entry Base Address Register (MTVEC)

CSR address: 0x305

| Bit    | Name     | Access | Description  | Reset value |
|--------|----------|--------|--|-------------|
| [31:2] | BASEADDR | MRW    | Interrupt vector table base address.   | 0           |
| 1      | MODE1    | MRW    | Interrupt vector scale recognition pattern.<br>1: Identified by absolute address, full range is supported, but must be redirected<br>0: Identified by jump instruction, limited range, support non-jump instruction. | 0           |
| 0      | MODE0    | MRW    | Interrupt or exception entry address mode selection.<br>1: Address offset according to interrupt number * 4<br>0: Use a unified entry address.   | 0           |

### 6.5.4 STK Register Description

Table 6-5 STK-related registers list

| Name          | Access address | Description                   | Reset value |

| [31:0] | CNT  | RW     | The current counter count value is 32 bits. | 0           |

### 6.5.4.4 Counting Comparison Register (STK\_CMPLR)

Offset address: 0x10

| Bit    | Name | Access | Description                                  | Reset value |
|--------|------|--------|--|-------------|
| [31:0] | CMP  | RW     | Set the comparison counter value to 32 bits. | 0           |

## Chapter 7 GPIO and Alternate Function (GPIO/AFIO)

The module described in this chapter is suitable for the full range of CH32V00X microcontrollers.

The GPIO port can be configured in a variety of input or output modes, with built-in pull-up or pull-down resistors that can be closed, and can be configured for push-pull or open-drain functions. The GPIO port can also be reused into other functions.

### 7.1 Main Features

Each pin of the port can be configured to one of the following multiple modes

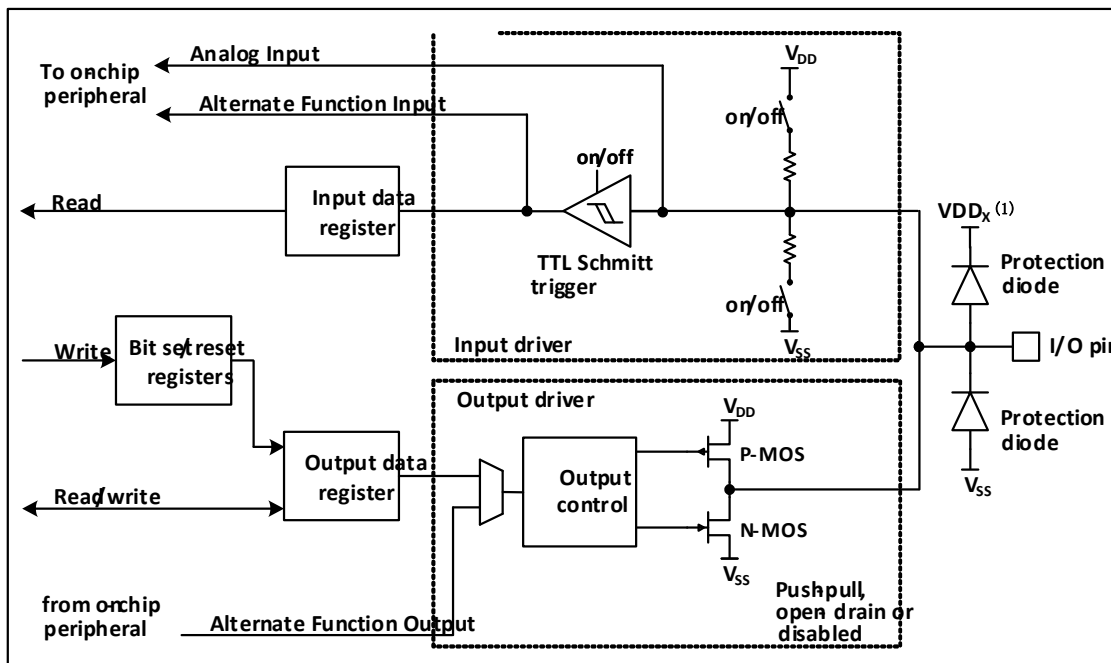

- Floating input
- Pull-up input
- Pull-down input
- Analog input
- Open-drain output
- Push-pull output
- Inputs and outputs of alternate functions

Many pins have the alternate function, and many other peripherals map their output and input channels to these pins. The specific usage of these alternate pins needs to refer to each peripheral. Whether these pins are reused and remapped is explained in this chapter.

### 7.2 Function Description

#### 7.2.1 Overview

Figure 7-1 GPIO module basic structure block diagram

Note: (1) VDDx is VDD when GPIO is normal IO, and VDDx is VDD\_FT when GPIO is FTIO.

As shown in figure 7-1, the IO port structure, each pin has two protection diodes inside the chip, and the IO port can be divided into input and output drive modules. The input driver has a weak pull-up resistor, which can be connected to AD and other analog input peripherals; if you input to a digital peripheral, you need to go through a

TTL Schmitt trigger, and then connect to the GPIO input register or other multiplexed peripherals. The output driver has a pair of MOS tubes, and the IO port can be configured to open-drain or push-pull output by configuring whether the upper and lower MOS tubes are enabled or not; the output driver can also be configured to be controlled by GPIO or by other peripherals that are reused.

### 7.2.2 GPIO Initialization Function

Just after the reset, the GPIO port is running in the initial state, at this time, most IO ports are running in the floating input state, but there are also HSE and other peripheral-related pins that run on the peripheral reuse function. For specific initialization functions, please refer to the relevant sections of the pin description.

### 7.2.3 External Interrupts

All GPIO ports can be configured with external interrupt input channels, but an external interrupt input channel can only be mapped to one GPIO pin, and the sequence number of the external interrupt channel must be consistent with the tag of the GPIO port, such as PA1 (Or PC1, PD1, etc.) can only be mapped to EXTI1, and EXTI1 can only accept the mapping of one of PA1, PC1 or PD1, etc., both sides are one-to-one relationship.

### 7.2.4 Alternate Functions

When using the alternate function, you must pay attention to:

- Using the alternate function of the input direction, the port must be configured in the alternate input mode, and the up and down settings can be set according to the actual needs.
- Using the alternate function in the output direction, the port must be configured in the multiplexing output mode, and push-pull or open-drain can be set according to the actual situation.
- For bi-directional alternate, the port must be configured for multiplexed output mode, in which case the driver is configured for floating input mode

Multiple peripherals may be reused to this pin in the same IO port, so in order to maximize the exertion space of each peripheral, the alternate pin of the peripheral can be remapped and remapped to other pins to avoid the occupied pins in addition to the default alternate pin.

### 7.2.5 Locking Mechanism

The locking mechanism can lock the configuration of the IO port. After a specific write sequence, the selected IO pin configuration is locked and cannot be changed until the next reset.

### 7.2.6 Input Configuration

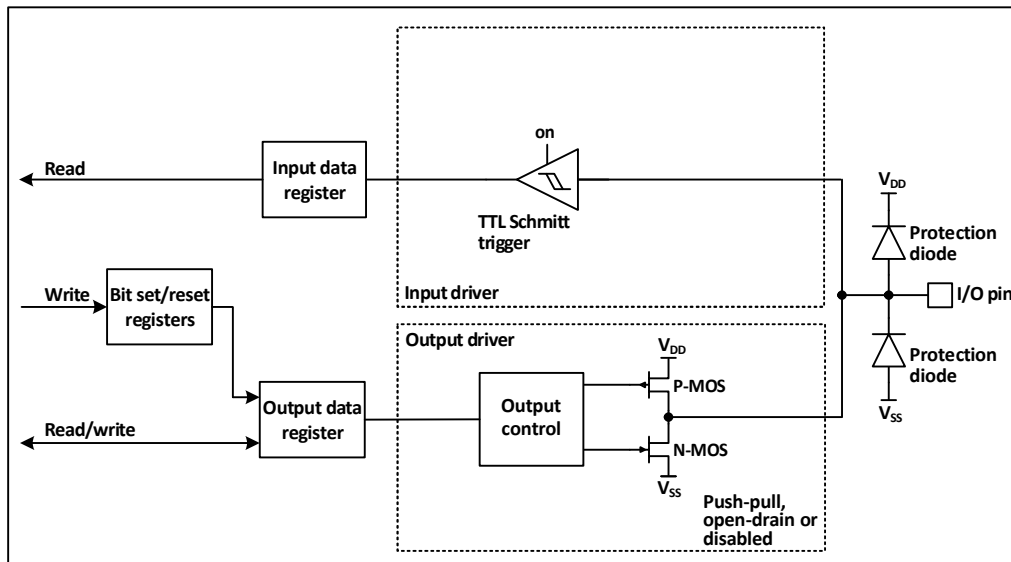

Figure 7-2 GPIO module input configuration structure block diagram

When the IO port is configured in input mode, the output driver is disconnected, the input up and down is optional, and the alternate function and analog input are not connected. The data on each IO port is sampled to the input data register at each HB clock, and the level state of the corresponding pin is obtained by reading the corresponding bit of the input data register.

### 7.2.7 Output Configuration

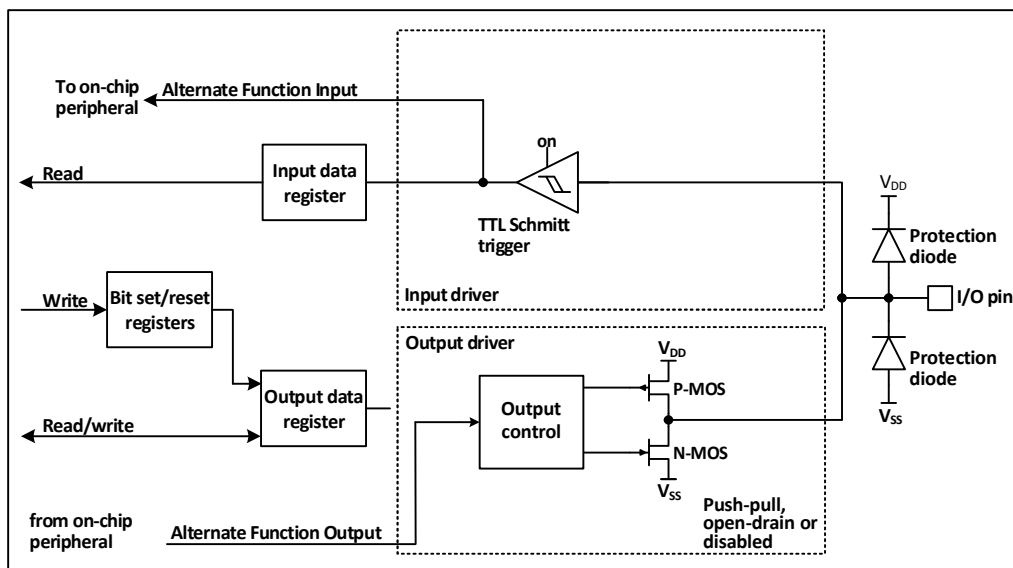

Figure 7-3 GPIO module output configuration structure block diagram

When the IO port is configured in output mode, a pair of MOS in the output driver can be configured in push-pull or open-drain mode as needed, without using the alternate function. The input-driven pull-up resistor is disabled, the TTL Schmitt trigger is activated, and the level that appears on the IO pin will be sampled to the input data register at each HB clock, so reading the input data register will get the IO state, and in push-pull output mode, access to the output data register will get the last written value.

### 7.2.8 Alternate Function Configuration

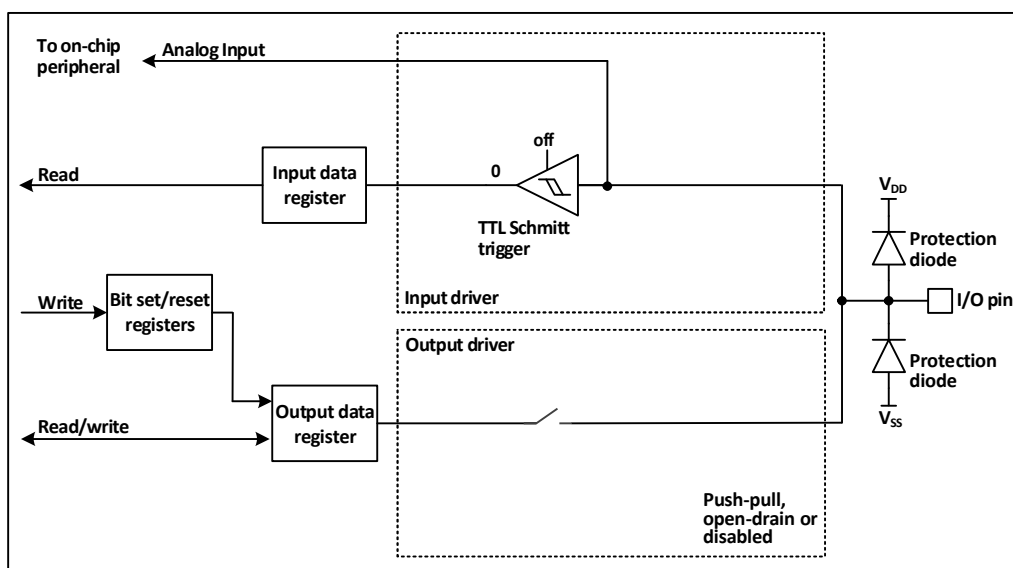

Figure 7-4 The structure of GPIO module when it is multiplexed by other peripherals

When the alternate function is enabled, the output driver is enabled and can be configured in open-drain or push-pull mode as needed, the Schmitt trigger is also turned on, the input and output lines of the alternate function are connected, but the output data register is disconnected, and the level that appears on the IO pin will be sampled to the input data register at each HB clock. In open-drain mode, reading the input data register will get the current state of the IO port. In push-pull mode, reading the output data register will get the last written value.

### 7.2.9 Analog Input Configuration

Figure 7-5 The configuration structure when the GPIO module is used as an analog input

When the analog input is enabled, the output buffer is disconnected, the input of the Schmitt trigger in the input driver is disabled to prevent consumption on the IO port, the pull-up resistor is prohibited, and the read input data register will always be 0.

## 7.2.10 GPIO Settings for Peripherals

The following table recommends the corresponding GPIO port configuration for the pins of each peripheral.

Table 7-1 Advanced-control timer (TIM1)

| TIM1      | Configuration                    | GPIO configuration         |
|-----------|----------------------------------|----------------------------|
| TIM1_CHx  | Input capture channel x          | Floating input             |
|           | Output comparison channel x      | Push-pull alternate output |
| TIM1_CHxN | Complementary output channels x  | Push-pull alternate output |
| TIM1_BKIN | Brake input                      | Floating input             |
| TIM1_ETR  | Externally triggered clock input | Floating input             |

Table 7-2 General-purpose timer (TIM2)

| TIM2 pin | Configuration                    | GPIO configuration         |
|----------|----------------------------------|----------------------------|
| TIM2_CHx | Input capture channel x          | Floating input             |
|          | Output comparison channel x      | Push-pull alternate output |
| TIM2_ETR | Externally triggered clock input | Floating input             |

Table 7-3 Universal synchronous asynchronous serial transceiver (USART)

| USART pins | Configuration                | GPIO configuration              |
|------------|------------------------------|---------------------------------|
| USARTx_TX  | Full-duplex mode             | Push-pull alternate outputs     |
|            | Half-duplex synchronous mode | Open-drain alternate outputs    |
| USARTx_RX  | Full-duplex mode             | Floating input or pull-up input |
|            | Half-duplex synchronous mode | Not used                        |
| USARTx_RTS | Hardware flow control        | Push-pull alternate output      |
| USARTx_CTS | Hardware flow control        | Floating input or pull-up input |

Table 7-4 Serial peripheral interface (SPI) modules

| SPI pins  | Configuration                               | GPIO configuration              |
|-----------|---|---------------------------------|
| SPIx_SCK  | Master mode                                 | Push-pull alternate output      |
|           | Slave mode                                  | Floating input                  |
| SPIx_MOSI | Full-duplex Master mode                     | Push-pull alternate output      |
|           | Full-duplex Slave mode                      | Floating input or pull-up input |
|           | Simple bi-directional data line/Master mode | Push-pull alternate output      |
|           | Simple bi-directional data line/Slave mode  | Not used                        |
| SPIx_MISO | Full-duplex Master mode                     | Floating input or pull-up input |
|           | Full-duplex Slave mode                      | Push-pull alternate output      |
|           | Simple bi-directional data line/Master mode | Not used                        |
|           | Simple bi-directional data line/Slave mode  | Push-pull alternate output      |

|          |   |                                   |
|----------|---|-----------------------------------|
| SPIx_NSS | Hardware Master or Slave mode               | Float, pull-up or pull-down input |
|          | Hardware Master mode/NSS output enable mode | Push-pull alternate output        |
|          | Software mode                               | Not used                          |

Table 7-5 Internal integrated bus (I2C) module

| I2C pins | Configuration | GPIO configuration          |
|----------|---------------|-----------------------------|
| I2C_SCL  | I2C clock     | Open-drain alternate output |

| I2C_SDA            | PC1                           | PD0                     | PC4                     | PB6                           | PD1                     |

### 7.2.11.5 ADC Alternate Function Remapping

Table 7-14 ADC external trigger injection conversion alternate function remapping

| Alternate function                        | ADC_ETRGINJ_RM=0<br>Default mapping                      | ADC_ETRGINJ_RM=1<br>Remapping                            |
|---|--|--|
| ADC external trigger injection conversion | ADC external trigger injection conversion connect to PD1 | ADC external trigger injection conversion connect to PA2 |

Table 7-15 ADC external trigger rule conversion alternate function remapping

| Alternate function                   | ADC_ETRGREG_RM=0<br>Default mapping                 | ADC_ETRGREG_RM=1<br>Remapping                       |
|--------------------------------------|---|---|
| ADC external trigger rule conversion | ADC external trigger rule conversion connect to PD3 | ADC external trigger rule conversion connect to PC2 |

## 7.3 Register Description

### 7.3.1 GPIO Register Description

Unless otherwise specified, the registers of the GPIO must be operated as words (Operate these registers with 32 bits).

Table 7-16 GPIO-related registers list

| Name            | Access address | Description                         | Reset value |
|-----------------|----------------|-------------------------------------|-------------|
| R32_GPIOA_CFGLR | 0x40010800     | PA Port Configuration Register Low  | 0x44444444  |
| R32_GPIOB_CFGLR | 0x40010C00     | PB Port Configuration Register Low  | 0x44444444  |
| R32_GPIOC_CFGLR | 0x40011000     | PC Port Configuration Register Low  | 0x44444444  |
| R32_GPIOD_CFGLR | 0x40011400     | PD Port Configuration Register Low  | 0x44444444  |
| R32_GPIOA_INDR  | 0x40010808     | PA Port Input Data Register         | 0x000000XX  |
| R32_GPIOB_INDR  | 0x40010C08     | PB Port Input Data Register         | 0x000000XX  |
| R32_GPIOC_INDR  | 0x40011008     | PC Port Input Data Register         | 0x000000XX  |

|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

| Bit    | Name     | Access | Description  | Reset value |
|--------|----------|--------|--|-------------|
| [31:8] | Reserved | RO     | Reserved   | 0           |
| [7:0]  | BRy      | WO     | (y=0-7), the corresponding OUTDR bits are cleared for these bits, and writing 0 has no effect. These bits can only be accessed in the form of 16 bits. | 0           |

**7.3.1.6 Port Configuration Lock Register (GPIOx\_LCKR) (x=A/B/C/D)**

Offset address: 0x18

| Bit     | Name     | Access | Description  | Reset value |
|---------|----------|--------|--|-------------|
| [31:17] | Reserved | RO     | Reserved   | 0           |
| 16      | LCKK     | RW     | Lock key, which can be locked by writing a specific sequence, but it can be read out at any time. When it reads 0, it means that the lock is not in effect, and read 1 means that the lock is in effect. The write sequence of the lock key is: write 1-write 0-write 1-read 0-read 1, the last step is not necessary, but can be used to confirm that the lock key has been activated. Any error when writing a sequence does not activate a lock, and the value of LCK [7:0] cannot be changed when writing a sequence. After the lock is in effect, the configuration of the port can be changed only after the next reset. | 0           |
| [15:8]  | Reserved | RO     | Reserved   | 0           |
| [7:0]   | LCKy     | RW     | (y=0-7), where 1 indicates that the configuration of the corresponding port is locked. These bits can only be changed before the LCKK is locked. Locked configurations refer to the configuration registers GPIOx_CFGLR and GPIOx_CFGHR.   | 0           |

*Note: When the LOCK sequence is executed on the corresponding port bit, the configuration of the port bit will not be changed until the next system reset.*

### 7.3.2 AFIO Register Description

Unless otherwise specified, AFIO registers must be operated as words (operate these registers with 32 bits).

Table 7-17 List of AFIO-related registers

| Name            | Access address | Description                                 | Reset value |
|-----------------|----------------|---|-------------|

## Chapter 8 Direct Memory Access Control (DMA)

*The module described in this chapter is suitable for the full range of CH32V00X microcontrollers.*

Direct memory access controller (DMA) provides a high-speed data transfer mode between peripherals and memory or between memory and memory. Without CPU intervention, data can be moved quickly through DMA to save CPU resources for other operations.

Each channel of the DMA controller is dedicated to managing requests for memory access from one or more peripherals. There is also an arbitrator to coordinate priorities between channels.

### 8.1 Main Features

- Multiple independently configurable channels
- Each channel is directly connected to dedicated hardware DMA requests and supports software triggering.
- Buffer management supporting loops
- The priority of the request between multiple channels can be set by software programming (Highest, high, medium and low). When the priority setting is equal, it is determined by the channel number (The lower the channel number, the higher the priority).
- Support peripherals to memory, memory to peripherals, and memory to memory transfer
- Flash memory, SRAM, SRAM of peripherals and HB peripherals can be used as sources and destinations for access
- Number of programmable data transfer bytes: Up to 65535

### 8.2 Function Description

#### 8.2.1 DMA Channel Processing

##### 1) Arbitration priority

DMA requests generated by multiple independent channels are logically or structurally input to the DMA controller, and currently only one channel request is answered. The arbitrator within the module selects the access of the peripheral / memory to be initiated according to the priority of the channel request.

In software management, applications can independently configure priority levels for each channel, including the highest, high, medium and low levels, by setting the PL [1:0] bit of the DMA\_CFGRx register. When the software settings between the channels are the same, the modules will be selected according to the fixed hardware priority, and the lower channel number will have higher priority than the higher one.

##### 2) DMA configuration

When the DMA controller receives a request signal, it accesses the requesting peripheral or memory to establish the peripheral or data transfer between the memory and the memory. It mainly includes the following three steps:

- 1) Data is taken from the memory address indicated by the peripheral data register or the current peripheral / memory address register, and the starting address of the first transmission is the peripheral base address or memory address specified by the DMA\_PADDRx or DMA\_MADDRx register.
- 2) The data is stored in the peripheral data register or the memory address indicated by the current peripheral / memory address register, and the starting address of the first transmission is the peripheral base address or memory address specified in the DMA\_PADDRx or DMA\_MADDRx register.
- 3) Performs a decrement operation of values in a DMA\_CNTRx register that indicates the number of operations

currently outstanding for transfer.

Each channel includes three DMA data transfer methods:

- Peripheral to memory (MEM2MEM=0, DIR=0)
- Memory to peripheral (MEM2MEM=0, DIR=1)
- Memory to memory (MEM2MEM=1)

*Note: The memory-to-memory mode does not require peripheral request signals. After configuring this mode (MEM2MEM=1), the channel can be opened (EN=1) to start data transmission. Circular mode is not supported in this way.*

The configuration process is as follows:

- 1) The first address of the peripheral register or the memory data address in the memory-to-memory mode (MEM2MEM=1) is set in the DMA\_PADDRx register. When an DMA request occurs, this address will be the source or destination address of the data transfer.
- 2) Set the memory data address in the DMA\_MADDRx register. When a DMA request occurs, the transmitted data will be read from or written to this address.
- 3) Set the amount of data to be transferred in the DMA\_CNTRx register. After each data transmission, this value decreases.
- 4) Set the priority of the channel in the PL [1:0] bit of the DMA\_CFGRx register.
- 5) The direction of data transmission, loop mode, incremental mode of peripherals and memory, data width of peripherals and memory, more than half of transmission, transmission completion, and transmission error interrupt enable bit are set in the DMA\_CFGRx register.
- 6) Set the EN bit of the DMA\_CFGRx register to start channel x.

*Note: The control bits in the DMA\_PADDRx/DMA\_MADDRx/DMA\_CNTRx register and the data transfer direction (DIR), loop mode (location), peripheral and memory incremental mode (MINC/PINC) in the DMA\_CFGRx register can be configured to write only when the DMA channel is turned off.*

### 3) Circular mode

Set the CIRC location 1 of the DMA\_CFGRx register to enable the circular mode function of channel data transfer. In circular mode, when the number of data transfers becomes 0, the contents of the DMA\_CNTRx register are automatically reloaded to their initial values, the internal peripherals and memory address registers are also reloaded to the initial address values set by the DMA\_PADDRx and DMA\_MADDRx registers, and the DMA operation continues until the channel is closed or DMA mode is turned off.

### 4) DMA processing status

- Transfer more than half: corresponding to the HTIFx bit hardware setting in the DMA\_INTFR register. When the number of transmission bytes of DMA is reduced to less than half of the initial setting value, more than half of the DMA transfer flag will be generated, and if HTIE is set in the DMA\_CFGRx register, an interrupt will occur. The hardware uses this flag to remind the application that it can prepare for a new round of data transfer.
- Transfer completed: corresponding to the TCIFx bit hardware setting in the DMA\_INTFR register. When the number of transfer bytes of DMA is reduced to 0, the DMA transfer completion flag will be generated, and if TCIE is set in the DMA\_CFGRx register, an interrupt will occur.
- Transmission error: corresponding to the TEIFx bit hardware setting in the DMA\_INTFR register. Reading and writing a reserved address area will result in a DMA transmission error. At the same time, the module

hardware will automatically clear the EN bits of the DMA\_CFGRx register corresponding to the channel where the error occurred, and the channel is closed. If TEIE is set in the DMA\_CFGRx register, an interrupt will occur.

When querying the status of the DMA channel, the application can first access the GIFx bit of the DMA\_INTFR register, determine which channel has the DMA event, and then deal with the specific DMA event content of the channel.

### 8.2.2 Programmable Total Data Transfer Size/Data Bit Width/Alignment

The total amount of data transmitted by DMA in one round of each channel is programmable, up to 65535 times. The DMA\_CNTRx register indicates the number of bytes to be transferred. In EN=0, the setting value is written, and after the EN=1 opens the DMA transmission channel, the register becomes read-only, and the value decreases after each transfer.

The transmission data values of peripherals and memory support the function of automatic increment of address pointer, and the pointer increment is programmable. The first transmitted data address they access is stored in the DMA\_PADDRx and DMA\_MADDRx registers. By setting the PINC bit or MINC location 1 of the DMA\_CFGRx register, you can turn on the peripheral address self-increment mode or the memory address self-increment mode, respectively. PSIZE [1:0] sets the peripheral address to take data size and address self-increase, and MSIZE [1:0] sets the memory address to take data size and address self-increase. There are 3 options: 8-bit, 16-bit, 32-bit. The specific data transfer methods are as follows:

Table 8-1 DMA transfer with different data bit widths (PINC=MINC=1)

| Source bit width | Objectives bit width | Transmission number | Source: address/data                             | Target: address/data   | Transfer operations   |

### 8.2.3 DMA Request Mapping

The DMA controller provides 7 channels, and each channel corresponds to multiple peripheral requests. By setting the corresponding DMA control bit in the corresponding peripheral register, the DMA function of each peripheral can be turned on or off independently. The specific correspondence is as follows.

Figure 8-1 DMA1 request image

Table 8-2 DMA1 peripheral mapping table for each channel

| Peripheral | Channel 1                  | Channel 2               | Channel 3               | Channel 4                         | Channel 5               | Channel 6               | Channel 7            |
|------------|----------------------------|-------------------------|-------------------------|-----------------------------------|-------------------------|-------------------------|----------------------|
| ADC        | ADC                        |                         |                         |                                   |                         |                         |                      |
| SPI1       |                            | SPI1_RX                 | SPI1_TX                 |                                   |                         |                         |                      |
| USART1     |                            |                         |                         | USART1_TX                         | USART1_RX               |                         |                      |
| USART2     |                            |                         |                         |                                   |                         | USART2_TX               | USART2_RX            |
| I2C1       |                            |                         |                         |                                   |                         | I2C1_TX                 | I2C1_RX              |
| TIM1       |                            | TIM1_CH1                | TIM1_CH2                | TIM1_CH4<br>TIM1_TRIG<br>TIM1_COM | TIM1_UP                 | TIM1_CH3                |                      |
| TIM2       | TIM2_CH3                   | TIM2_UP                 |                         |                                   | TIM2_CH1                |                         | TIM2_CH2<br>TIM2_CH4 |
| TIM3       | TIM3_CH3 <sup>(1)(2)</sup> | TIM3_CH3 <sup>(1)</sup> | TIM3_CH3 <sup>(1)</sup> | TIM3_CH4 <sup>(1)(2)</sup>        | TIM3_CH4 <sup>(1)</sup> | TIM3_CH4 <sup>(1)</sup> |                      |

Note:

(1) The TIM3 of CH32M007 generates a CH3 event, which can trigger channels 1, 2 and 3 of DMA1, and TIM3 generates an CH3 event that can trigger channels 4, 5 and 6 of DMA1.

(2) TIM3 of CH32V006 and CH32V007 generates one CH3 event, which can only trigger channel 1 of DMA1; TIM3 generates one CH4 event, which can only trigger channel 4 of DMA1.

## 8.3 Register Description

Table 8-3 DMA-related registers list

| Name           | Access address | Description                                 | Reset value |
|----------------|----------------|---|-------------|

## Chapter 9 Analog-to-digital Converter (ADC)

*The module described in this chapter is suitable for the full range of CH32V00X microcontrollers.*

The ADC module contains a 12-bit analog-to-digital converter that provides up to 8 external channels and 3 internal channels for sampling at rates up to 3Msps. It can complete the functions of single conversion, continuous conversion, automatic scanning mode, discontinuous mode, external trigger mode and so on. The channel voltage can be monitored by simulating the watchdog function. When the monitoring voltage exceeds the set threshold, the reset and protection system can be configured.

### 9.1 Main Features

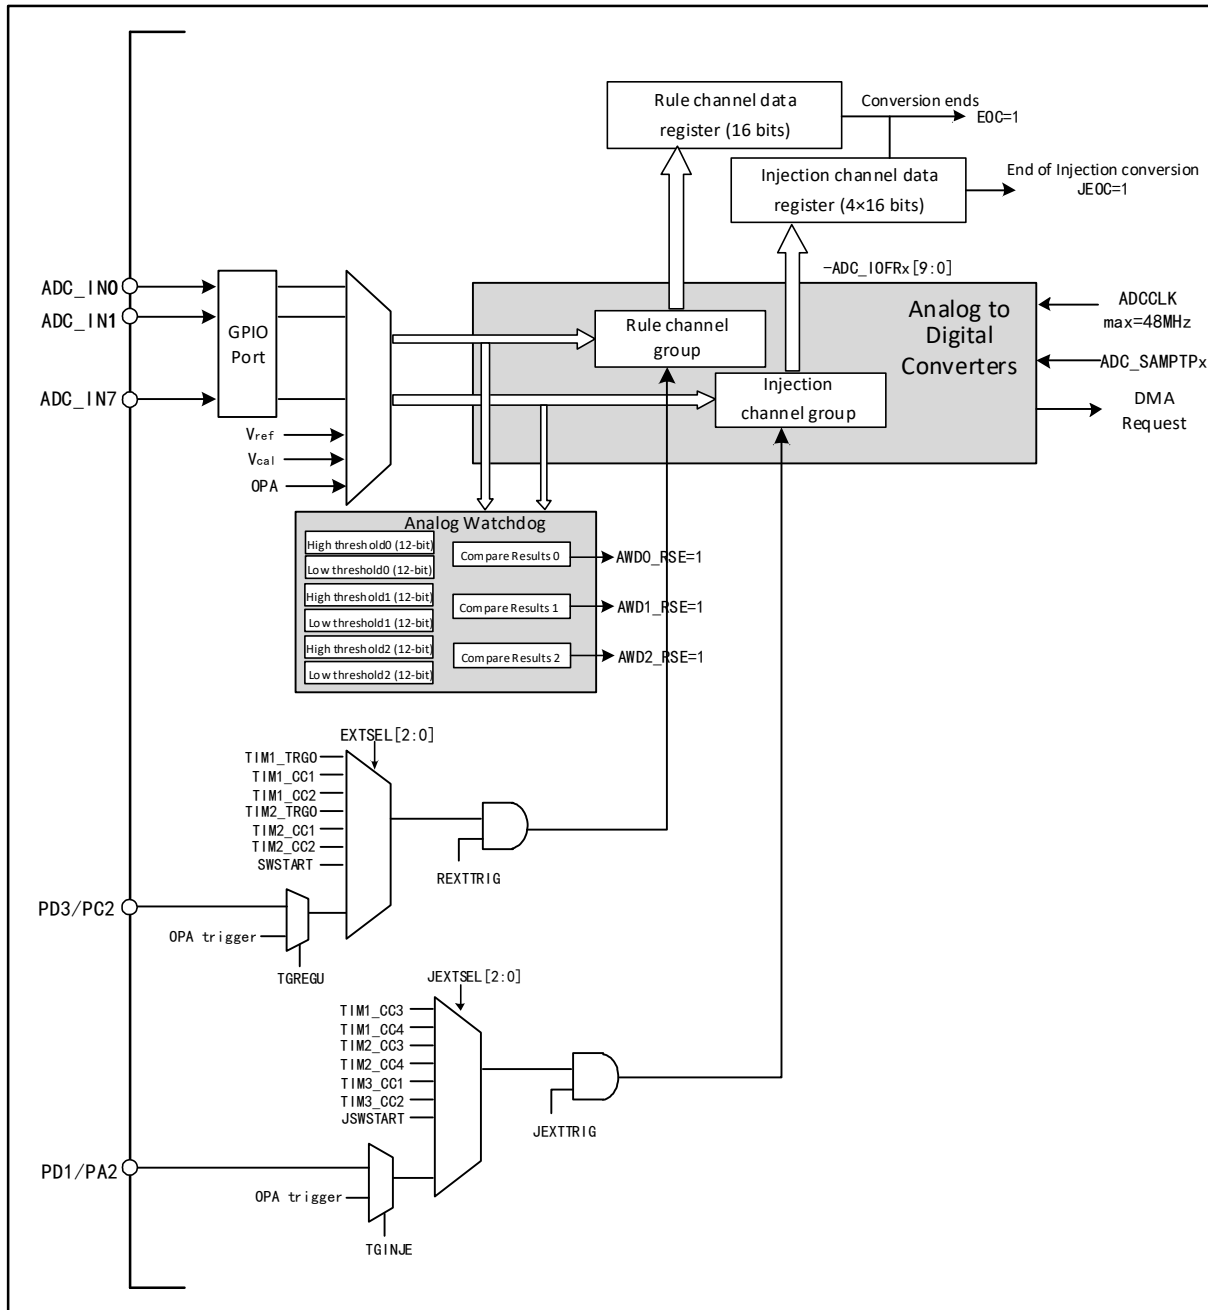

- 12-bit resolution
- Supports 8 external channels and 3 internal signal sources for sampling
- Multiple sampling conversion methods for multiple channels: Single, continuous, scan, trigger, intermittent, etc.
- Data alignment modes: Left-aligned, right-aligned
- Sampling time can be programmed separately by channel
- Both rule conversion and injection conversion support external triggering
- Analog watchdog to monitor channel voltage, self-calibration function
- ADC channel input range:  $0 \leq V_{IN} \leq V_{DD}$

## 9.2 Functional Description

### 9.2.1 Module Structure

Figure 9-1 ADC module block diagram

### 9.2.2 ADC Configuration

#### 1) Module power-up

An ADON bit of 1 in the ADC\_CTLR2 register indicates that the ADC module is powered up. When the ADC module enters the power-up state (ADON=1) from the power-off mode (ADON=0), it needs to be delayed for a period of time for  $t_{STAB}$  to stabilize the module. After that, the ADON bit is written again as 1, which is used as the startup signal for the software to start the ADC conversion. By clearing the ADON bit to 0, you can terminate the current conversion and put the ADC module in power-down mode, where ADC consumes almost no power.

## 2) Sampling clock

The register operation of the module is based on the HBCLK (HB bus) clock, and the clock reference of its conversion unit, ADCCLK, is configured by the ADCPRE field of the RCC\_CFGR0 register to divide the frequency.

## 3) Channel configuration

The ADC module provides 11 channel sampling sources, including 8 external channels and 3 internal channels. They can be configured into two translation groups: rule groups and injection groups. To realize the group conversion consisting of a series of transformations in any order on any number of channels.

Conversion group:

- Rule group: consists of up to 16 conversions. The rule channels and their conversion order are set in the ADC\_RSQRx register. The total number of conversions in the rule group should be written to L[3:0] in the ADC\_RSQR1 register.
- Injection group: consists of up to 4 conversions. The injection channels and the order of their conversions are set in the ADC\_ISQR register. The total number of conversions in the injection group should be written in JL[1:0] of the ADC\_ISQR register.

*Note: If the ADC\_RSQRx or ADC\_ISQR registers are changed during conversion, the current conversion is terminated and a new start signal is sent to the ADC to convert the newly selected group.*

3 internal channels.

- Vref internal reference voltage: Connected to ADC\_IN8 channel.
- OPA internal output channel: Connected the ADC\_IN9 channel, which is used to convert the output of OPA to numeric values.
- Vcal internal calibration voltage: Connected to ADC\_IN10 channel, half the voltage of the power supply.

## 4) Calibration

The ADC has a built-in self-calibration mode. A calibration session significantly reduces accuracy errors due to variations in the internal capacitor banks. During calibration, an error correction code is calculated on each capacitor, which is used to eliminate the errors generated on each capacitor in subsequent conversions.

Initialize the calibration register by writing RSTCAL position 1 of ADC\_CTLR2 register and wait for RSTCAL hardware to clear 0 to indicate the completion of initialization. Set the CAL bit to start the calibration function. Once the calibration is finished, the hardware will automatically clear the CAL bit and store the calibration code into ADC\_RDATAR. After that, the normal conversion function can be started. It is recommended to perform an ADC calibration when the ADC module is powered up.

*Note: Before starting the calibration, you must ensure that the ADC module is in the power-up state (ADON=1) for more than at least two ADC clock cycles.*

## 5) Programmable sampling time

The ADC uses several ADCCLK cycles to sample the input voltage. The number of sampling cycles for a channel can be changed using the SMPx[2:0] bits in the ADC\_SAMPTR1 and ADC\_SAMPTR2 registers. Each channel can be sampled separately using a different time.

The total conversion time is calculated as follows.

$$T_{CONV} = \text{sampling time} + 12.5 T_{ADCLK}$$

The ADC's rule channel conversion supports the DMA function. The value of the rule channel conversion is stored in a data-only register, ADC\_RDATAR. To prevent the data in ADC\_RDATAR register from being fetched in time

when multiple rule channels are converted in succession, the DMA function of ADC can be enabled. The hardware will generate a DMA request at the end of the conversion of a rule channel (EOC set) and transfer the converted data from the ADC\_RDATAR register to the user-specified destination address.

After the channel configuration of the DMA controller module is completed, write DMA position 1 of the ADC\_CTLR2 register to enable the DMA function of the ADC.

*Note: Injection group conversion does not support DMA function.*

**6) Data alignment**

The ALIGN bit in the ADC\_CTLR2 register selects the alignment of the ADC converted data storage. 12-bit data supports left-aligned and right-aligned modes.

The data register ADC\_RDATAR of the rule group channel holds the actual converted 12-bit digital value; while the data register ADC\_IDATARx of the injection group channel is the actual converted data minus the value written after the offset defined in the ADC\_IOFRx register, there will be positive and negative cases, so there are sign bits (SIGNB).

Table 9-1 Data left alignment

Rule group data register

|     |     |    |    |    |    |    |    |    |    |    |    |   |   |   |   |

|-------|-------|-------|-------|-----|-----|----|----|----|----|----|----|----|----|----|----|

**9.2.3 External Trigger Source**

The ADC conversion start event can be triggered by an external event. If the EXTTRIG or JEXTTRIG bits of the ADC\_CTLR2 register are set, the conversion of a rule group or injection group channel can be triggered by an external event, respectively. In this case, the configuration of EXTSEL[2:0] and JEXTSEL[2:0] bits determines the external event source for the rule group and injection group.

*Note: When an external trigger signal is selected for ADC rule or injection conversion, only its rising edge can start the conversion.*

Table 9-3 External trigger sources for rule group channels

| EXTSEL[2:0] | Trigger source        | Type                               |
|-------------|-----------------------|------------------------------------|
| 000         | TRGO event of timer 1 | Internal signal from on-chip timer |
| 001         | CC1 event of timer 1  |                                    |
| 010         | CC2 event of timer 1  |                                    |
| 011         | TRGO event of timer 2 |                                    |
| 100         | CC1 event of timer 2  |                                    |

|     |                          |                       |
|-----|--------------------------|-----------------------|
| 101 | CC2 event of timer 2     |                       |
| 110 | OPA trigger/ (PD3/PC2)   | From external pins    |
| 111 | SWSTART software trigger | Software control bits |

Table 9-4 External trigger sources for injection group channels

| JEXTSEL[2:0] | Trigger source            | Type                               |
|--------------|---------------------------|------------------------------------|
| 000          | CC3 event of timer 1      | Internal signal from on-chip timer |
| 001          | CC4 event of timer 1      |                                    |
| 010          | CC3 event of timer 2      |                                    |
| 011          | CC4 event of timer 2      |                                    |
| 100          | CC1 event of timer 3      |                                    |
| 101          | CC2 event of timer 3      |                                    |
| 110          | OPA trigger/ (PD1/PA2)    | From external pins                 |
| 111          | JSWSTART software trigger | Software control bits              |

### 9.2.4 Conversion Mode

Table 9-5 Conversion mode combinations

| ADC_CTLR1 and ADC_CTLR2 register control bit |      |                 |       |  | ADC conversion mode  |
|--|------|-----------------|-------|--|--|
| CONT   | SCAN | RDISCEN/IDISCEN | JAUTO | Startup event                              |  |
| 0  | 0    | 0               | 0     | ADON position 1                            | Single single-channel mode: A rule channel performs a single conversion.   |
|  |      |                 |       | External trigger method                    | Single single-channel mode: A single conversion is performed on one of the rule channels or injection channels.  |
|  | 1    | 0               | 0     | ADON position 1 or external trigger method | Single scan mode: performs a single conversion of all selected rule group channels (ADC_RSQRx) or all injection group channels (ADC_ISQR) one by one in sequence.<br>Trigger injection method: When the rule group channel conversion process can be inserted into the injection group channel all conversion, and then continue the rule group channel conversion afterwards; but the rule group channel conversion will not be inserted when converting the injection group channel. |
|  |      |                 |       | ADON position 1 or external trigger method | Single scan mode: performs a single conversion of all selected rule group channels (ADC_RSQRx) or all injection group channels (ADC_ISQR) one by one in sequence.<br>Automatic injection method: After the rule group channel is converted, the injection group  |
|  |      |                 | 1     | ADON position 1 or external trigger method |  |

|   |   |   |                         |  |  |
|---|---|---|-------------------------|--|--|
|   |   |   |                         |  | channel is automatically converted.<br><i>Note: External trigger signals injected into the channel are not allowed during conversion.</i>  |
| 0 | 1<br>(RDISCEN and IDISCEN cannot both be 1) | 0 | External trigger method |  | Single intermittent mode: Each time an event is started, a short sequence (DISCNUM[2:0] defined number) of channel number transitions is executed and cannot be restarted until all selected channel transitions are completed.<br><i>Note: The IDISCEN and RDISCEN control bits are selected for the rule group and injection group respectively, and the intermittent mode cannot be configured for the rule group and injection group at the same time.</i> |
|   |   |   |                         | 1  | -  |
|   | 1   | 1 | X                       | -  | No such mode.  |
| 1 | 0   | 0 | 0                       | ADON position 1 or external trigger method | Continuous single channel/scan mode: repeat a new round of transitions at the end of each round until CONT clears 0 to terminate.  |
|   | 1   | 0 | 1                       |  |  |

*Note: The external trigger events for rule groups and injection groups are different, and the 'ACON' bit can only initiate Rule Group channel transitions, so the initiation events for Rule Group and Injection Group channel transitions are independent.*

**1) Single single-channel conversion mode**

In this mode, only one conversion is performed for the current 1 channel. This mode performs conversion on the channels sorted first in the rule group or injection group, where it can be started by setting ADON position 1 of the ADC\_CTLR2 register (for regular channels only) or by external triggering (for regular channels or injection channels). Once the conversion of the selected channel is completed:

If the rule group channel is converted, the conversion data is stored in the 16-bit ADC\_RDATAR register, the EOC flag is set, and if the EOCIE bit is set, the ADC interrupt will be triggered.

If the injection group channel is converted, the conversion data is stored in the 16-bit ADC\_IDATAR1 register, the EOC and JEOC flags are set, and if the JEOCIE or EOCIE bit is set, the ADC interrupt will be triggered.

**2) Single scan mode conversion**

Enter ADC scan mode by setting the scan bit of the ADC\_CTLR1 register to 1. This mode is used to scan a set of analog channels and perform a single conversion one by one for all channels selected by the ADC\_RSQRx register (for regular channels) or ADC\_ISQR (for injection channels). When the current channel conversion ends, the next channel of the same group is automatically converted.

In the scanning mode, according to the state of JAUTO bits, it can be divided into trigger injection mode and automatic injection mode.

- **Trigger injection**

The JAUTO bit is 0, when the trigger event of the injection group channel conversion occurs in the process of

scanning the rule group channel, the current conversion is reset, and the sequence of the injection channel is carried out in a single scan mode. After all the selected injection group channel scan conversion is completed, the last interrupted rule group channel conversion is restored.

If the start event of the regular channel occurs when scanning the channel sequence of the injection group, the conversion of the injection group will not be interrupted, but the conversion of the rule sequence will be performed after the conversion of the injection sequence is completed.

*Note: When using triggered injection transformations, you must ensure that the interval between triggered events is longer than the injection sequence. For example, if it takes 28 ADCCLK to complete the conversion of the injection sequence, the minimum time between events to trigger the injection channel is 29 ADCCLK.*

- Auto-injection

The JAUTO bit is 1, and after scanning all the channel translations selected by the rule group, the channel selected by the injection group is converted automatically. This method can be used to convert up to 20 conversion sequences in ADC\_RSQRx and ADC\_ISQR registers.

In this mode, the external trigger (JEXTTRIG=0) of the injection channel must be disabled.

*Note: When the ADC clock pre-division factor (ADCPRE [1:0]) is 4 to 8, 1 ADCCLK interval is automatically inserted when switching from regular conversion to injection sequence or from injection conversion to regular sequence; when the ADC clock pre-division factor is 2, there is a delay of 2 ADCCLK intervals.*

### 3) Single intermittent mode conversion

Enter the break mode of the rule group or injection group by setting the RDISCEN or IDISCEN bit of the ADC\_CTLR1 register to 1. This mode distinguishes scanning a complete set of channels in the scan mode, but divides a group of channels into multiple short sequences, and each external trigger event will perform a scan conversion of a short sequence.

The length of the short sequence  $n$  ( $n \leq 8$ ) is defined in the DISCNUM [2:0] of the ADC\_CTLR1 register. When RDISCEN is 1, it is the discontinuous mode of the rule group, and the total length to be converted is defined in the L [3:0] of the ADC\_RSQR1 register. When IDISCEN is 1, it is the discontinuous mode of the injection group, and the total length to be converted is defined in the JL [1:0] of the ADC\_ISQR register. Both rule group and injection group cannot be set to discontinuous mode at the same time.

Example of rule group discontinuity mode:

RDISCEN=1, DISCNUM[2:0]=3, L[3:0]=8, channels to be converted=1, 3, 2, 5, 8, 4, 10, 6

The 1st external trigger: conversion sequence is: 1, 3, 2

The 2nd external trigger: conversion sequence is: 5, 8, 4

The 3rd external trigger: conversion sequence is: 10, 6, while generating EOC events

The 4th external trigger: conversion sequence is: 1, 3, 2

Example of injection group intermittent mode:

IDISCEN=1, DISCNUM[2:0]=1, JL[1:0]=3, channels to be converted=1, 3, 2

The 1st external trigger: conversion sequence is: 1

The 2nd external trigger: the conversion sequence is: 3

The 3rd external trigger: conversion sequence is: 2, generating both EOC and JEEOC events

The 4th external trigger: conversion sequence is: 1

*Note: 1. When a rule group or injection group is converted in intermittent mode, the conversion sequence does not automatically start from scratch at the end of the conversion sequence. When all subgroups are converted, the next trigger event initiates the conversion of the first subgroup.*

*2. You cannot use auto-injection (JAUTO=1) and intermittent mode at the same time.*

*3. You cannot set intermittent mode for both rule groups and injection groups, and intermittent mode can only*

be used for a group of conversions.

#### 4) Continuous conversion

In the continuous conversion mode, another conversion is started as soon as the previous ADC conversion is completed. The conversion will not stop on the last channel of the selection group, but will continue conversion from the first channel of the selection group again. The startup events in this mode include external trigger events and the ADON bit is set to 1. After setting the startup, the CONT bit needs to be set to 1.

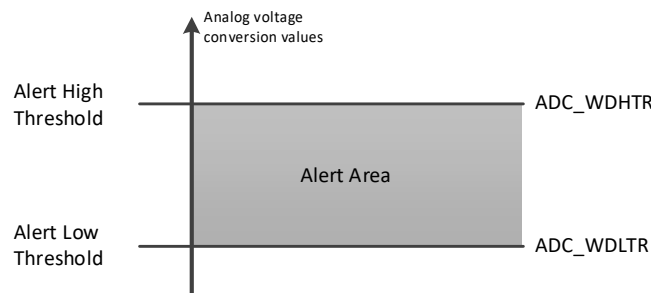

If a rule channel is converted, the conversion data is stored in the ADC\_RDATAR register, the conversion end flag EOC is set, and if EOCIE is set, an interrupt is generated.

If an injection channel is converted, the conversion data is stored in the ADC\_IDATARx register, the injection conversion end flag JEOC is set, and if JEOCIE is set, an interrupt is generated.

### 9.2.5 Analog Watchdog

If the analog voltage converted by the ADC is lower than the low threshold or higher than the high threshold, the AWD analog watchdog status bit is set. The threshold setting is located in the lowest 12 significant bits of the ADC\_WDHTR and ADC\_WDLTR registers. The corresponding interrupt is allowed by setting the AWDIE bit of the ADC\_CTLR1 register.

Figure 9-4 Analog watchdog threshold area

Configure the AWDSGL, AWDEN, JAWDEN and AWDCH[4:0] bits of the ADC\_CTLR1 register to select the channel for analog watchdog alerting, as related in the following table.

Table 9-6 Analog Watchdog channel selection

| Analog watchdog alert channel   | ADC_CTLR1 register control bit |       |        |                              |
|---------------------------------|--------------------------------|-------|--------|------------------------------|
|                                 | AWDSGL                         | AWDEN | JAWDEN | AWDCH[4:0]                   |
| No vigilance                    | Ignore                         | 0     | 0      | Ignore                       |
| All injection channels          | 0                              | 0     | 1      | Ignore                       |
| All rule channels               | 0                              | 1     | 0      | Ignore                       |
| All injection and rule channels | 0                              | 1     | 1      | Ignore                       |
| Single injection channel        | 1                              | 0     | 1      | Determine the channel number |
| Single rule channel             | 1                              | 1     | 0      | Determine the channel number |

| Single injection and rule channel | 1 | 1 | 1 | Determine the channel number |
|-----------------------------------|---|---|---|------------------------------|

### 9.3 Register Description

Table 9-7 ADC-related registers list

| Name            | Access address | Description                                  | Reset value |
|-----------------|----------------|--|-------------|
| R32_ADC_STATR   | 0x40012400     | ADC Status Register                          | 0x00000000  |
| R32_ADC_CTLR1   | 0x40012404     | ADC Control Register 1                       | 0x00000000  |
| R32_ADC_CTLR2   | 0x40012408     | ADC Control Register 2                       | 0x00000000  |
| R32_ADC_SAMPTR1 | 0x4001240C     | ADC Sample Time Configuration Register 1     | 0x00000000  |
| R32_ADC_SAMPTR2 | 0x40012410     | ADC Sample Time Configuration Register 2     | 0x00000000  |
| R32_ADC_IOFR1   | 0x40012414     | ADC Injection Channel Data Offset Register 1 | 0x00000000  |
| R32_ADC_IOFR2   | 0x40012418     | ADC Injection Channel Data Offset Register 2 | 0x00000000  |
| R32_ADC_IOFR3   | 0x4001241C     | ADC Injection Channel Data Offset Register 3 | 0x00000000  |
| R32_ADC_IOFR4   | 0x40012420     | ADC Injection Channel Data Offset Register 4 | 0x00000000  |
| R32_ADC_WDHTR   | 0x40012424     | ADC Watchdog High Threshold Register         | 0x00000FFF  |
| R32_ADC_WDLTR   | 0x40012428     | ADC Watchdog Low Threshold Register          | 0x00000000  |
| R32_ADC_RSQR1   | 0x4001242C     | ADC Rule Sequence Register 1                 | 0x00000000  |
| R32_ADC_RSQR2   | 0x40012430     | ADC Rule Sequence Register 2                 | 0x00000000  |
| R32_ADC_RSQR3   | 0x40012434     | ADC Rule Sequence Register 3                 | 0x00000000  |
| R32_ADC_ISQR    | 0x40012438     | ADC Injection Sequence Register              | 0x00000000  |
| R32_ADC_IDATAR1 | 0x4001243C     | ADC Injection Data Register 1                | 0x00000000  |
| R32_ADC_IDATAR2 | 0x40012440     | ADC Injection Data Register 2                | 0x00000000  |
| R32_ADC_IDATAR3 | 0x40012444     | ADC Injection Data Register 3                | 0x00000000  |
| R32_ADC_IDATAR4 | 0x40012448     | ADC Injection Data Register 4                | 0x00000000  |
| R32_ADC_RDATAR  | 0x4001244C     | ADC Rule Data Register                       | 0x00000000  |
| R32_ADC_CTLR3   | 0x40012450     | ADC Control Register 3                       | 0x00000001  |
| R32_ADC_WDTR1   | 0x40012454     | ADC Watchdog 1 Threshold Register            | 0x0FFF0000  |
| R32_ADC_WDTR2   | 0x40012458     | ADC Watchdog 2 Threshold Register            | 0x0FFF0000  |

#### 9.3.1 ADC Status Register (ADC\_STATR)

Offset address: 0x00

|          |    |    |    |    |    |    |    |    |    |    |      |           |      |     |     |
|----------|----|----|----|----|----|----|----|----|----|----|------|-----------|------|-----|-----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20   | 19        | 18   | 17  | 16  |
| Reserved |    |    |    |    |    |    |    |    |    |    |      |           |      |     |     |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4    | 3         | 2    | 1   | 0   |
| Reserved |    |    |    |    |    |    |    |    |    |    | STRT | JSTR<br>T | JEOC | EOC | AWD |

| Bit    | Name     | Access | Description   | Reset value |
|--------|----------|--------|---|-------------|
| [31:5] | Reserved | RO     | Reserved  | 0           |
| 4      | STRT     | RW0    | Rule channel transition start state.<br>1: Rule channel conversion has started.<br>0: Rule channel conversion is not started.<br>This bit is set to 1 by hardware and cleared to 0 by software (write 1 is not valid).  | 0           |
| 3      | JSTRT    | RW0    | Injection channel conversion start state.<br>1: Injection channel conversion has started.<br>0: Injection channel conversion has not started.<br>This bit is set to 1 by hardware and cleared to 0 by software (write 1 is not valid).  | 0           |
| 2      | JEOC     | RW0    | Injection channel group conversion completed status.<br>1: Conversion completed;<br>0: Conversion is not completed.<br>This bit is set to 1 by hardware (all injected channels are converted) and cleared to 0 by software (write 1 is invalid).                                | 0           |
| 1      | EOC      | RW0    | Conversion end status.<br>1: Conversion completed;<br>0: Conversion is not completed.<br>This bit is set to 1 by hardware (end of rule or injection channel group conversion), cleared by software to 0 (write 1 is invalid) or when reading ADC_RDATAR.                        | 0           |
| 0      | AWD      | RW0    | Analog watchdog flag bit.<br>1: Occurrence of analog watchdog events.<br>0: No analog watchdog event occurred.<br>This bit is set to 1 by hardware (conversion value is out of range of ADC_WDHTR and ADC_WDLTR registers) and cleared to 0 by software (write 1 is not valid). | 0           |

### 9.3.2 ADC Control Register 1 (ADC\_CTLR1)

Offset address: 0x04

|              |    |    |         |        |       |         |          |        |        |          |            |    |    |    |    |  |
|--------------|----|----|---------|--------|-------|---------|----------|--------|--------|----------|------------|----|----|----|----|--|
| 31           | 30 | 29 | 28      | 27     | 26    | 25      | 24       | 23     | 22     | 21       | 20         | 19 | 18 | 17 | 16 |  |
| Reserved     |    |    |         |        | BUFEN | TKITUNE | TKENABLE | AWDEN  | JAWDEN | Reserved |            |    |    |    |    |  |
| 15           | 14 | 13 | 12      | 11     | 10    | 9       | 8        | 7      | 6      | 5        | 4          | 3  | 2  | 1  | 0  |  |
| DISCNUM[2:0] |    |    | JDISCEN | DISCEN | JAUTO | AWDSGL  | SCAN     | JEOCIE | AWDIE  | EOCIE    | AWDCH[4:0] |    |    |    |    |  |

| Bit     | Name     | Access | Description                   | Reset value |
|---------|----------|--------|-------------------------------|-------------|
| [31:27] | Reserved | RO     | Reserved                      | 0           |
| 26      | BUFEN    | RW     | ADC BUF enable.<br>1: Enable; | 0           |

|         |              |    |   |   |
|---------|--------------|----|---|---|
|         |              |    | 0: Disable.   |   |
| 25      | TKITUNE      | RW | Touchkey current adjustment.<br>1: 17.5 $\mu$ A;<br>0: 35 $\mu$ A.  | 0 |
| 24      | TKENABLE     | RW | TKEY module enable control.<br>1: Enable TKEY module;<br>0: Disable TKEY module.  | 0 |
| 23      | AWDEN        | RW | Analog watchdog function enable bit on the rule channel.<br>1: Enable analog watchdog on the rule channel;<br>0: Disable analog watchdog on the rule channel.   | 0 |
| 22      | JAWDEN       | RW | Analog watchdog function enable bit on the injection channel.<br>1: Enable analog watchdog on the injection channel;<br>0: Disable analog watchdog on the injection channel.  | 0 |
| [21:16] | Reserved     | RO | Reserved  | 0 |
| [15:13] | DISCNUM[2:0] | RW | Number of rule channels to be converted after external triggering in intermittent mode.<br>000: 1 channel.<br>...<br>111: 8 channels.   | 0 |
| 12      | JDISCEN      | RW | Intermittent mode enable bit on the injection channel.<br>1: Enable intermittent mode on the injection channel;<br>0: Disable intermittent mode on the injection channel.   | 0 |
| 11      | DISCEN       | RW | Intermittent mode enable bit on the rule channel.<br>1: Enable intermittent mode on the rule channel;<br>0: Disable intermittent mode on the rule channel.  | 0 |
| 10      | JAUTO        | RW | Upon completion of opening a rule channel, the injection channel group enable bit is automatically converted.<br>1: Enable automatic injection channel group conversion;<br>0: Disable automatic injection channel group conversion.<br><i>Note: This mode requires disabling the external trigger function of the injection channel.</i> | 0 |
| 9       | AWDSGL       | RW | In scan mode, use the analog watchdog enable bit on a single channel.<br>1: Use analog watchdog on a single channel (AWDCH[4:0] selection);<br>0: Use analog watchdog on all channels.  | 0 |
| 8       | SCAN         | RW | Scan mode enable bit.<br>1: Enable scan mode (Continuously convert all channels selected by ADC_IOFRx and ADC_RSQRx);<br>0: Disable scan mode.  | 0 |
| 7       | JEOCIE       | RW | The injection channel group conversion ends the interrupt enable bit.<br>1: Enable injection channel group conversion completion  | 0 |

|       |            |    |   |   |
|-------|------------|----|---|---|
|       |            |    | interrupt (JEOC flag);<br>0: Disable injection channel group conversion completion interrupt.   |   |
| 6     | AWDIE      | RW | Analog watchdog interrupt enable bit.<br>1: Enable analog watchdog interrupt;<br>0: Disable analog watchdog interrupt.<br><i>Note: In scan mode, if this interruption occurs, the scan will be aborted.</i> | 0 |
| 5     | EOCIE      | RW | The conversion ends (rule or injection channel group) interrupt enable bit.<br>1: Enable conversion end interrupt (EOC flag)<br>0: Disable conversion end interrupt.  | 0 |
| [4:0] | AWDCH[4:0] | RW | Analog watchdog channel selection bit.<br>00000: Analog input channel 0;<br>00001: Analog input channel 1;<br>...<br>01111: Analog input channel 15.  | 0 |

### 9.3.3 ADC Control Register 2 (ADC\_CTLR2)

Offset address: 0x08

|              |              |    |           |          |    |     |          |    |                 |                  |             |             |          |          |              |
|--------------|--------------|----|-----------|----------|----|-----|----------|----|-----------------|------------------|-------------|-------------|----------|----------|--------------|
| 31           | 30           | 29 | 28        | 27       | 26 | 25  | 24       | 23 | 22              | 21               | 20          | 19          | 18       | 17       | 16           |

| JEXT<br>TRIG | JEXTSEL[2:0] |    | ALIG<br>N | Reserved |    | DMA | Reserved |    | TGINJ<br>E      | TGRE<br>GU       | RST<br>CAL  | CAL         | CON<br>T | ADO<br>N |              |

| Bit     | Name     | Access | Description  | Reset value |
|---------|----------|--------|--|-------------|
| [31:23] | Reserved | RO     | Reserved   | 0           |
| 22      | SWSTART  | RW     | Initiates a rule channel conversion, need to set software trigger.<br>1: Startup rule channel conversion;<br>0: Reset status.<br>This bit is set by software and cleared to 0 by hardware when conversion starts.            | 0           |
| 21      | JSWSTART | RW     | Initiates an injection channel conversion, need to set software trigger.<br>1: Startup injection channel conversion;<br>0: Reset status.<br>This bit is set by software and cleared to 0 by hardware when conversion starts. | 0           |
| 20      | EXTTRIG  | RW     | External trigger conversion mode enabled on rule channel.<br>1: Enable the external event startup function;  | 0           |

|         |              |    |  |   |
|---------|--------------|----|--|---|
|         |              |    | 0: Disable the external event startup function.  |   |
| [19:17] | EXTSEL[2:0]  | RW | Initiates external trigger event selection of rule channel conversion.<br>000: TRGO event of timer 1;<br>001: CC1 event of timer 1;<br>010: CC2 event of timer 1;<br>011: TRGO event of timer 2;<br>100: CC1 event of timer 2;<br>101: CC2 event of timer 2;<br>110: OPA trigger/ (PD3/PC2);<br>111: SWSTART software trigger.     | 0 |
| 16      | Reserved     | RO | Reserved   | 0 |
| 15      | JEXTTRIG     | RW | External trigger conversion mode enabled of injection channel.<br>1: Use external events to initiate conversions;<br>0: Disable external event initiation.   | 0 |
| [14:12] | JEXTSEL[2:0] | RW | Initiates external trigger event selection of injection channel conversion.<br>000: CC3 event of timer 1;<br>001: CC4 event of timer 1;<br>010: CC3 event of timer 2;<br>011: CC4 event of timer 2;<br>100: CC1 event of timer 3;<br>101: CC2 event of timer 3;<br>110: OPA trigger/ (PD1/PA2);<br>111: JSWSTART software trigger. | 0 |
| 11      | ALIGN        | RW | Data alignment.<br>1: Left-aligned; 0: Right-aligned.  | 0 |
| [10:9]  | Reserved     | RO | Reserved   | 0 |
| 8       | DMA          | RW | Direct Memory Access (DMA) mode enable.<br>1: Enable DMA mode.<br>0: Disable DMA mode.   | 0 |
| [7:6]   | Reserved     | RO | Reserved   | 0 |
| 5       | TGINJE       | RW | External trigger event of injection channel conversion (JEXTSEL[2:0]=110) OPA trigger selection bit.<br>1: OPA trigger;<br>0: PD1/PA2.   | 0 |
| 4       | TGREGU       | RW | External trigger event of rule channel conversion (EXTSEL[2:0]=110) OPA trigger selection bit.<br>1: OPA trigger;<br>0: PD3/PC2.   | 0 |
| 3       | RSTCAL       | RW | Reset calibration, this bit is set by software and cleared to 0 by hardware when reset is complete.<br>1: Initialize the calibration register;   | 0 |

|   |      |    |  |   |
|---|------|----|--|---|
|   |      |    | 0: The calibration register is initialized.<br><i>Note: If RSTCAL is set while a conversion is in progress, clearing the calibration register requires an additional cycle.</i>  |   |
| 2 | CAL  | RW | A/D calibration, this bit is set by software and cleared to 0 by hardware at the end of calibration.<br>1: Start calibration;<br>0: Calibration complete.  | 0 |
| 1 | CONT | RW | Continuous conversion enable.<br>1: Continuous conversion mode;<br>0: Single conversion mode.<br>If this bit is set, conversion will be continuous until the bit is cleared.   | 0 |
| 0 | ADON | RW | Turns the A/D converter on/off.<br>When this bit is 0, writing 1 will wake up the ADC from power-down mode; when this bit is 1, writing 1 will start the conversion.<br>1: Turns the ADC on and initiates conversion;<br>0: turns off ADC conversion/calibration and enters power-down mode.<br><i>Note: A conversion is initiated when only ADON is changed in the register; if there are any other arbitrary bits sent for change, a new conversion will not be initiated.</i> | 0 |

### 9.3.4 ADC Sample Time Configuration Register 1 (ADC\_SAMPTR1)

Offset address: 0x0C

| Bit    | Name       | Access | Description   | Reset value |
|--------|------------|--------|---|-------------|
| [31:3] | Reserved   | RO     | Reserved  | 0           |
| [2:0]  | SMP10[2:0] | RW     | SMP10[2:0]: Sampling time configuration of channel 10.<br>In low power mode:<br>000: 3.5 cycles;                      001: 7.5 cycles;<br>010: 13.5 cycles;                    011: 28.5 cycles;<br>100: 41.5 cycles;                    101: 55.5 cycles;<br>110: 71.5 cycles;                    111: 239.5 cycles;<br>In non-low power mode:<br>000: 3.5 cycles;                      001: 7.5 cycles;<br>010: 11.5 cycles;                    011: 19.5 cycles;<br>100: 35.5 cycles;                    101: 55.5 cycles; | 0           |

### 9.3.12 ADC Injection Sequence Register (ADC\_ISQR)

Offset address: 0x38

|          |    |           |    |    |    |           |    |    |    |           |    |           |    |    |    |
|----------|----|-----------|----|----|----|-----------|----|----|----|-----------|----|-----------|----|----|----|
| 31       | 30 | 29        | 28 | 27 | 26 | 25        | 24 | 23 | 22 | 21        | 20 | 19        | 18 | 17 | 16 |
| Reserved |    |           |    |    |    |           |    |    |    | JL[1:0]   |    | JSQ4[4:1] |    |    |    |
| 15       | 14 | 13        | 12 | 11 | 10 | 9         | 8  | 7  | 6  | 5         | 4  | 3         | 2  | 1  | 0  |
| JSQ4[0]  |    | JSQ3[4:0] |    |    |    | JSQ2[4:0] |    |    |    | JSQ1[4:0] |    |           |    |    |    |

| Bit     | Name      | Access | Description  | Reset value |
|---------|-----------|--------|--|-------------|
| [31:22] | Reserved  | RO     | Reserved   | 0           |
| [21:20] | JL[1:0]   | RW     | The number of channels that need to be converted in the injection channel conversion sequence.<br>00-11: 1-4 conversions.  | 0           |
| [19:15] | JSQ4[4:0] | RW     | The number of the 4th conversion channel in the injection sequence (0-10).<br><i>Note: the software writes and assigns the channel number (0-10) to the 4th of the sequence to be converted.</i> | 0           |
| [14:10] | JSQ3[4:0] | RW     | The number of the 3rd conversion channel in the injection sequence (0-10).   | 0           |
| [9:5]   | JSQ2[4:0] | RW     | The number of the 2nd conversion channel in the injection sequence (0-10).   | 0           |
| [4:0]   | JSQ1[4:0] | RW     | The number of the 1st conversion channel in the injection sequence (0-10).   | 0           |

*Note: Unlike the regular conversion sequence, if the length of JL[1:0] is less than 4, the sequence order of conversion starts from (4 - JL).*

*For example, when JL[1:0]=3 (4 injected transitions in the sequencer), the ADC will convert channels in the following order: JSQ1[4:0], JSQ2[4:0], JSQ3[4:0], and JSQ4[4:0];*

*When JL[1:0]=2 (3 injected transitions in the sequencer), the ADC will convert the channels in the following order:*

JSQ2[4:0], JSQ3[4:0] and JSQ4[4:0];

When JL[1:0]=1 (2 injected conversions in the sequencer), the ADC converts the channels in the following order: first JSQ3[4:0], then JSQ4[4:0];

When JL[1:0] = 0 (1 injection conversion in the sequencer), the ADC will convert only the JSQ4[4:0] channels.

If ADCx\_ISQR[21:0]=10 00111 00011 00111 00010, the ADC will convert channels in the following order: JSQ2[4:0], JSQ3[4:0], and JSQ4[4:0], indicating that the scan conversions are performed in the following channel order: 7, 3, 7.

### 9.3.13 ADC Injection Data Register (ADC\_IDATARx) (x=1/2/3/4)

Offset address: 0x3C + (x-1)\*4

## Chapter 10 Touch Key Detection (TKEY)

*This chapter applies to the CH32V006, CH32V007, CH32M007.*

The touch detection control (TKEY) unit, with the help of the voltage conversion function of the ADC module, realizes the touch key detection function by converting the capacitance to the voltage for sampling. The detection channel reuses the 8 external channels of ADC, and the touch key detection is realized through the single conversion mode of the ADC module.

### 10.1 Functional Description

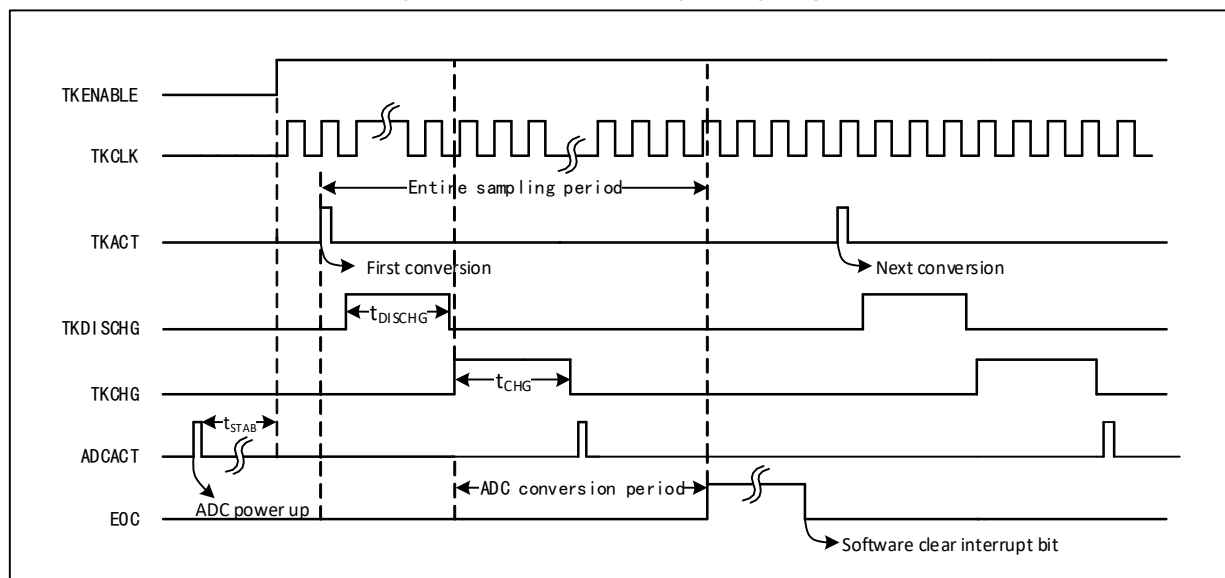

- Enable TKEY

The TKEY detection process needs the cooperation of the ADC module, so when using the TKEY function, it is necessary to ensure that the ADC module is in the power-on state (ADON=1), and then turn on the TKEY unit function by changing the TKENABLE position 1 of the ADC\_CTLR1 register, and the charging current of the TKEY module can be adjusted through the TKITUNE bit.

TKEY only supports single channel conversion mode. Configure the channel to be converted to the first rule group sequence of the ADC module, and the software starts the conversion (Write R32\_TKEY\_DISCHG register).

*Note: When the TKEY conversion is disabled, ADC channel configuration function can still be retained.*

Figure 10-1 TKEY working timing diagram

- Programmable sampling time

TKEY unit conversion needs to use several HBCLK clock cycles ( $t_{DISCHG}$ ) for discharge, and then charge and sample the voltage of the channel through several HBCLK cycles ( $t_{CHG}$ ). The number of discharge cycles is configured by register R32\_TKEY\_DISCHG, the number of charging cycles is configured by register R32\_TKEY\_CHG, and all channels use the same number of charge and discharge cycles.

### 10.2 TKEY Operations

TKEY detection is an extended function of ADC module. Its working principle is to change the capacitance sensed by the hardware channel through "touch" and "non-touch" methods, and then to convert the capacitance change into

the voltage change and finally convert into a digital value by the ADC module.

During sample, ADC needs to be configured as a single 1-channel working mode, and a conversion is started by the "write operation" of the R32\_TKEY\_DISCHG register. The specific process is as follows:

- 1) Initialize the ADC function, configure the ADC module as a single conversion module, set the ACON bit to 1, and wake up the ADC module. Set the TKENABLE bit in the ADC\_CTLR1 register to 1, and switch on the TKEY unit.
- 2) Set the channel to be converted, write the channel serial number into the first conversion position in the ADC regular group sequence (ADC\_RSQR3[4:0]), and set L[3:0] to 1.
- 3) Set the charge sample time of the channel, write to the R32\_TKEY\_CHG register, unit: HBCLK.
- 4) Write to R32\_TKEY\_DISCHG, set the discharge time, unit: HBCLK, to start a TKEY sample and conversion.
- 5) Wait for the EOC conversion end flag bit in the ADC status register to be set to 1, read the ADC\_DR register to obtain the conversion value.
- 6) To perform next conversion, repeat steps 2-5.

### 10.3 TKEY Register Description

Table 10-1 TKEY1 registers

| Name            | Access address | Description  | Reset value |
|-----------------|----------------|--|-------------|
| R32_TKEY_DISCHG | 0x4001243C     | TKEY Charge Time Configuration Register              | 0x00000000  |
| R32_TKEY_CHG    | 0x4001244C     | TKEY Start and Discharge Time Configuration Register | 0x00000000  |

| [15:0]  | DATA[15:0] | RO     | Converted data. | 0           |

*Note: This register maps the rule data register (ADC\_RDATAR) of the ADC module.*

## Chapter 11 Advanced-control Timer (ADTM)

*The module described in this chapter is suitable for the full range of CH32V00X microcontrollers.*

The Advanced Timer Module contains a powerful 16-bit auto-reload timer, TIM1, which can be used to measure pulse widths or to generate pulses, PWM waves, and more. It is used in motor control, power supply and other fields.

### 11.1 Main Features

The main features of the advanced timer TIM1 include:

- 16-bit automatic reinstall counter, supporting increasing counting mode, decreasing counting mode and increasing and decreasing counting mode
- 16-bit prescaler, frequency division coefficient is dynamically adjustable from 1 to 65536
- Support for four independent comparison capture channels.
- Each comparison capture channel supports multiple operating modes, such as: input capture, output comparison, PWM generation and single pulse output.
- Complementary outputs supporting programmable dead-time.
- Support external signals to control the timer.
- Support updating the timer after a defined period using a repeat counter.
- Support resetting the timer or placing it in the OK state using the brake signal.
- Support the use of DMA in multiple modes.
- Support incremental encoders.
- Support cascading and synchronization between timers.

### 11.2 Principle and Structure

This section deals with the internal construction of advanced-control timers.

#### 11.2.1 Overview

As shown in figure 11-1, the structure of the advanced timer can be roughly divided into three parts, namely, the input clock part, the core counter part and the comparison capture channel part.

The clock of the advanced-control timer can come from the HB bus clock (CK\_INT), from the external clock input pin (TIM1\_ETR), from other timers with clock output function (ITRx), or from the input of the comparison capture channel (TIM1\_CHx). After various set filtering and frequency division operations, these input clock signals become CK\_PSC clocks and output to the core counter. In addition, these complex clock sources can also be output as TRGO to other timers and ADC peripherals.

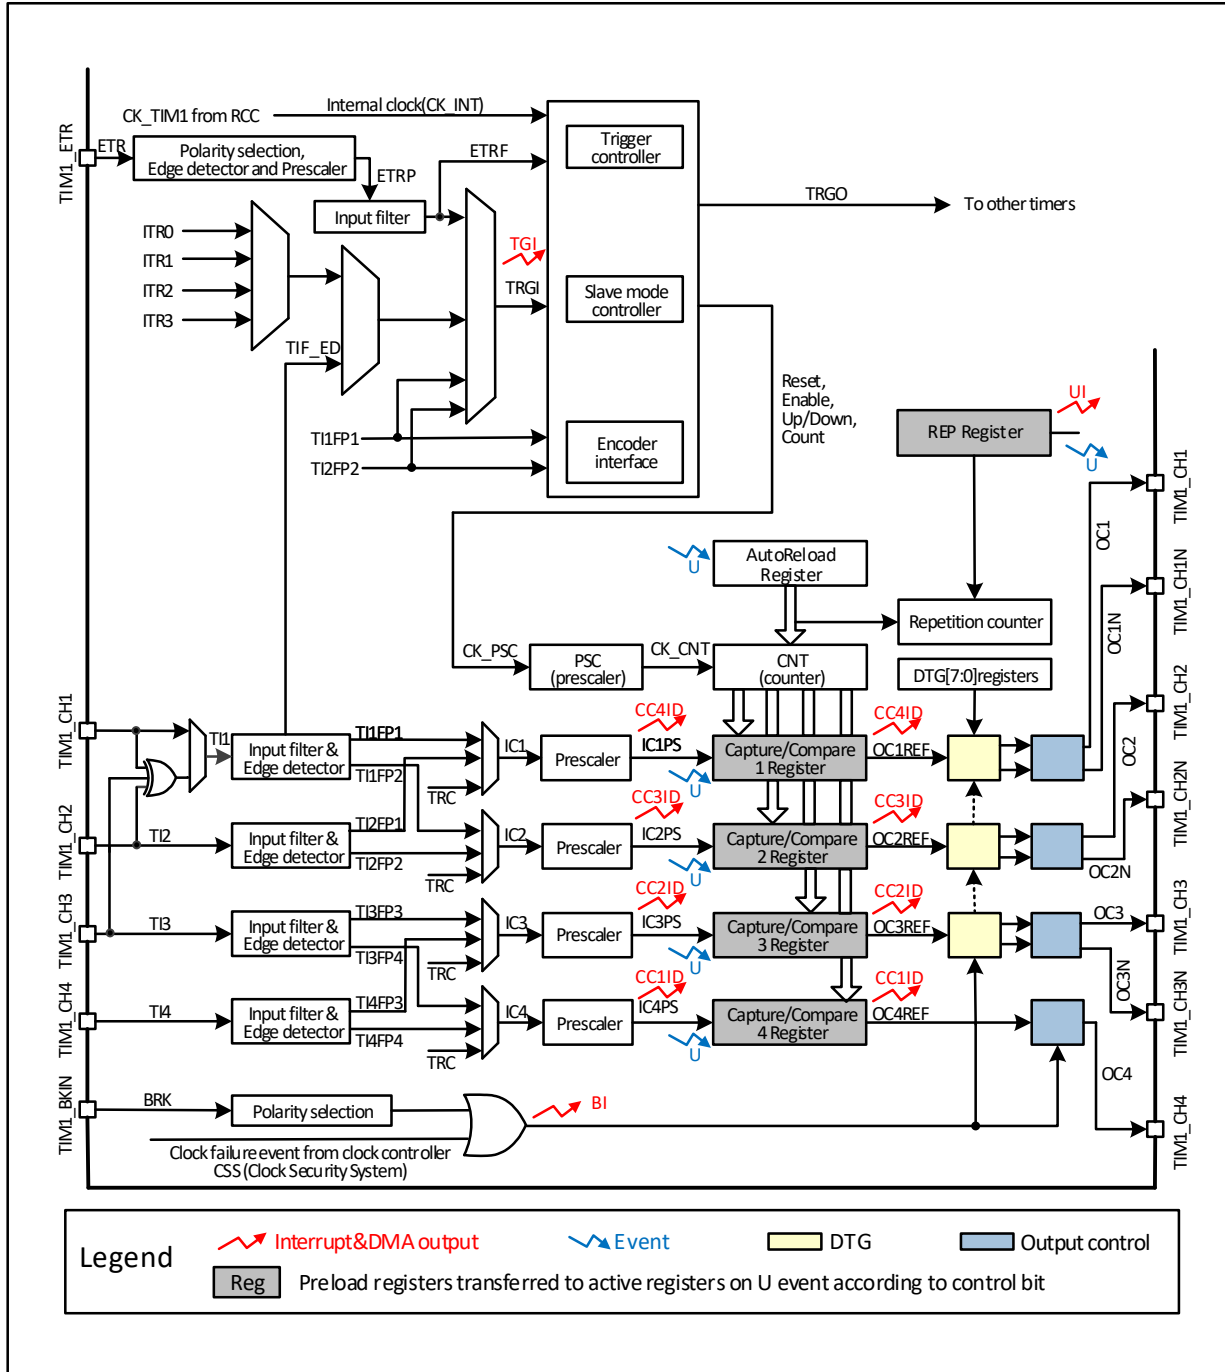

The core of the advanced timer is a 16-bit counter (CNT). After being divided by the prescaler (PSC), the CK\_PSC becomes CK\_CNT and output to CNT, CNT to support the increasing counting mode, decreasing counting mode and increasing or decreasing counting mode, and has an automatic reload value register (ATRLR) to reload the initial values for the CNT at the end of each counting cycle. There is also an auxiliary counter that counts the number of times ATRLR reloads initial values for CNT, which can generate specific events when the number of times reaches the number of times set in the repeated count register (RPTCR).

The advanced-control timer has four sets of comparison capture channels, each of which can input pulses from its own pin or output waveform to the pin, that is, the compare/capture channel supports input and output modes. The input of each channel of the compare/capture register supports operations such as filtering, frequency division and

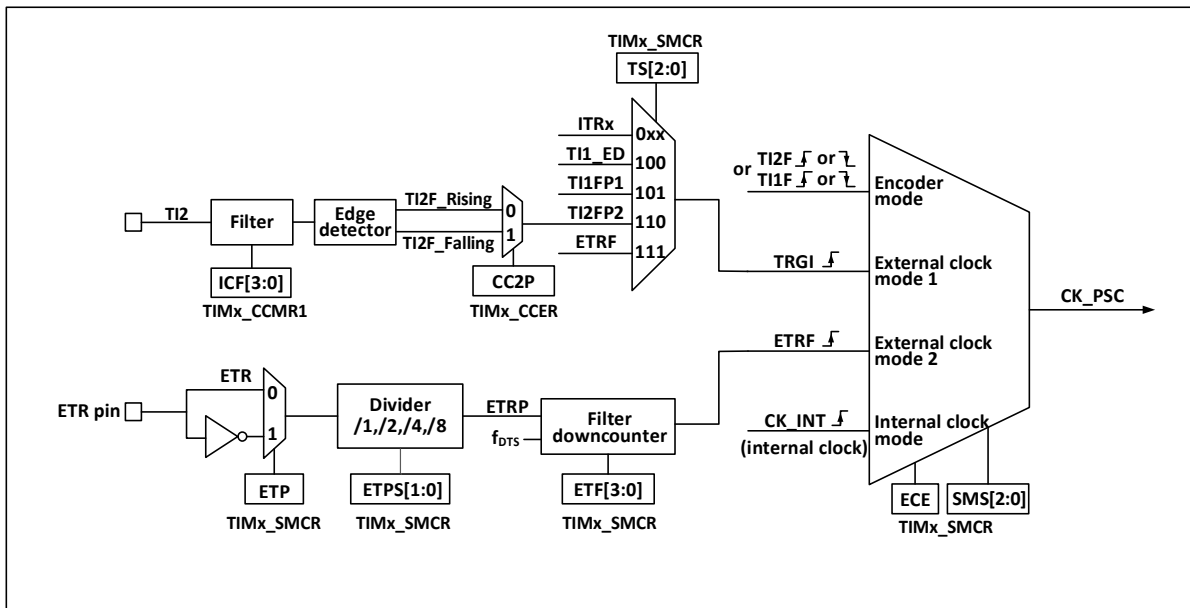

edge detection, supports mutual trigger between channels, and provides a clock for the core counter CNT. Each comparison acquisition channel has a set of comparison acquisition registers (CHxCVR) that support comparison with the master counter (CNT) to output pulses.

Figure 11-1 Block diagram of advanced-control timer structure

## 11.2.2 Clock Input

Figure 11-2 Block diagram of CK\_PSC source for advanced-control timer

Advanced-control timer CK\_PSC has many clock sources and can be divided into four categories:

- 1) The external clock pin (ETR) inputs the route of the clock: ETR→ETRP→ETRF;
- 2) Internal HB clock input route: CK\_INT;
- 3) Route from the comparison capture channel pin (TIM1\_CHx): TIM1\_CHx→Tix→TixFPx, this route is also used in encoder mode;
- 4) Input from other internal timers: ITRx;

By determining the input pulse selection of the SMS from which the CK\_PSC comes from, the actual operation can be divided into four categories:

- 1) Select internal clock source (CK\_INT);
- 2) External clock source mode 1;
- 3) External clock source mode 2;
- 4) Encoder mode;

All 4 clock sources mentioned above can be selected by these four operations.

### 11.2.2.1 Internal clock source (CK\_INT)

If the advanced timer is started when the SMS domain is kept at 000b, then the internal clock source (CK\_INT) is selected as the clock. At this point, CK\_INT is CK\_PSC.

### 11.2.2.2 External Clock Source Mode 1

If the SMS domain is set to 111b, external clock source mode 1 is enabled. When the external clock source 1 is enabled, TRGI is selected as the source of CK\_PSC, and it is worth noting that you also need to configure the TS domain to select the source of TRGI. The following pulses can be selected as clock sources in the TS domain:

- 1) Internal trigger (ITRx, x=0, 1, 2, 3)
- 2) The signal after compare/capture channel 1 through the edge detector (TI1F\_ED).
- 3) The signal TI1FP1, TI2FP2 of the compare/capture channel.

- 4) The signal ETRF from the external clock pin input.

### 11.2.2.3 External Clock Source Mode 2

Use external trigger mode 2 to count on every rising or falling edge of the external clock pin input. When the ECE position is set, the external clock source mode 2 is used. when using the external clock source mode 2, ETRF is selected as CK\_PSC. the ETR pin becomes ETRP after passing through the optional inverter (ETP), divider (ETPS), and then ETRF after passing through the filter (ETF).

With the ECE position bit and the SMS set to 111b, this is equivalent to the TS selecting ETRF as an input.

### 11.2.2.4 Encoder Mode

Setting the SMS to 001b, 010b, 011b will enable the encoder mode. Enabling encoder mode allows you to select a specific level in TI1FP1 and TI2FP2 to signal the output with another jump edge as the signal. This mode is used when an external encoder is used. Refer to Section 11.3.9 for specific functions.

## 11.2.3 Counters and Peripherals

CK\_PSC is input to the prescaler (PSC) for dividing. the PSC is 16-bit and the actual dividing factor is equal to the value of  $R16\_TIMx\_PSC + 1$ . CK\_PSC goes through the PSC and becomes CK\_INT. changing the value of R16\_TIM1\_PSC does not take effect in real time, but is updated to the PSC after an update event. the update event includes a UG bit clear and reset. The core of the timer is a 16-bit counter (CNT). CK\_CNT is eventually fed to the CNT, which supports incremental count mode, decremental count mode, and incremental and decremental count modes, and has an Automatic Reload Register (ATRLR) that reloads the initial value for the CNT at the end of each count cycle. There is also an auxiliary counter that keeps track of the number of times the ATRLR reloads the initial value for the CNT and can generate a specific event when the number of times set in the Repeat Count Register (RPTCR) is reached.

## 10.2.4 Compare/Capture Channels and Perimeters

The core of the timer is the compare/capture register, which is complemented by digital filtering, frequency division and inter-channel multiplexing in the peripheral input section, comparator and output control in the output section.

Figure 11-3 Block diagram of the structure of the compare/capture channel

The structure block diagram of the comparison capture channel is shown in Figure 10-3. The signal is input from the channel x pin and optionally made as TIx (the source of TI1 can be more than just CH1, see the structure block diagram of timer 11-1), TI1 is passed through the filter (ICF[3:0]) to generate TI1F, and then divided into TI1F\_Rising and TI1F\_Falling through the edge detector, these two signals are selected (CC1P) to generate TI1FP1,

TI1FP1 and TI2FP1 from channel 2 are sent together to CC1S to select to become IC1, which is sent to the comparison capture register after ICPS dividing.

The compare capture register consists of a preload register and a shadow register, and the read/write process operates only on the preload register. In capture mode, the capture occurs on the shadow register and is then copied to the preload register; in compare mode, the contents of the preload register are copied to the shadow register, and then the contents of the shadow register are compared to the core counter (CNT).

## 11.3 Function and Implementation

The implementation of the complex functions of the advanced-control timer are all achieved by the operation of the timer's compare/capture channel, clock input circuit and counter and peripheral parts. The clock input to the timer can come from multiple clock sources, including the input to the compare/capture channel. The operation of the compare/capture channel and clock source selection directly determines its function. The compare/capture channel is bidirectional and can operate in both input and output modes.

### 11.3.1 Input Capture Mode

The input capture mode is one of the basic functions of the timer. The principle of input capture mode is that a capture event occurs when a determined edge on the ICxPS signal is detected, and the current value of the counter is latched into the compare capture register (R16\_TIMx\_CHCTLRx). When a capture event occurs, CCxIF (in R16\_TIMx\_INTFR) is set, and if an interrupt or DMA is enabled, the corresponding interrupt or DMA is also generated. If CCxIF is already set when a capture event occurs, the CCxOF bit is set. CCxIF can be cleared by software, or by hardware by reading the compare capture register. CCxOF is cleared by software.

An example of channel 1 to illustrate the steps to use the input capture mode is as follows.

- 1) Configure the CCxS domain to select the source of the ICx signal. For example, set to 10b and select TI1FP1 as the source of IC1 instead of using the default setting, where the CCxS domain defaults to making the compare capture module the output channel.
- 2) Configure the ICxF domain to set the digital filter for the TI signal. The digital filter will sample the signal at a determined frequency, a determined number of times, and then output a hop. This sampling frequency and number of times is determined by ICxF.
- 3) Configure the CCxP bit to set the polarity of the TIxFPx. For example, keeping the CC1P bit low and selecting rising edge jumps.
- 4) Configure the ICxPS domain to set the ICx signal to be the crossover factor between ICxPS. For example, keeping ICxPS at 00b, without crossover.
- 5) Configure the CCxE bit to allow capturing the value of the core counter (CNT) into the compare capture register. Set the CC1E bit.
- 6) Configure the CCxIE and CCxDE bits as needed to determine whether to allow enable interrupts or DMA.

This completes the comparison capture channel configuration.

When a captured pulse is input to TI1, the value of the core counter (CNT) is recorded in the compare capture register, CC1IF is set, and the CC1OF bit is set when CC1IF has been set before. If the CC1IE bit is set, then an interrupt is generated; if CC1DE is set, a DMA request is generated. An input capture event can be generated by software by writing the event generation register (TIMx\_SWEVGR).

### 11.3.2 Compare Output Mode

The compare output mode is one of the basic functions of the timer. The principle of the compare output mode is to output a specific change or waveform when the value of the core counter (CNT) agrees with the value of the compare

capture register. the OCxM field (in R16\_TIMx\_CHCTLRx) and the CCxP bit (in R16\_TIMx\_CCER) determine whether the output is a definite high or low level or a level flip. The CCxIF bit is also set when a compare coherent event is generated. If the CCxIE bit is pre-set, an interrupt will be generated; if the CCxDE bit is pre-set, a DMA request will be generated.

To configure to compare output modes, proceed as follows.

- 1) Configuring the clock source and auto-reload value of the core counter (CNT).
- 2) Setting the count value to be compared to the comparison capture register (R32\_TIMx\_CHxCVR).
- 3) If an interrupt needs to be generated, set the CCxIE bit.
- 4) Keeping OCxPE at 0 to disable the preload register of the compare register.
- 5) Setting the output mode, setting the OCxM field and the CCxP bit.
- 6) Enable the output, setting the CCxE bit.
- 7) Set the CEN bit to start the timer.

### 11.3.3 Forced Output Mode

The output pattern of the timer's compare capture channel can be forced by software to output a determined level without relying on comparison of the compare capture register's shadow register with the core counter.

This is done by setting OCxM to 100b, which forces OCxREF to low, or by setting OCxM to 101b, which forces OCxREF to high.

Note that by forcing OCxM to 100b or 101b, the comparison process of the internal core counters and compare capture registers is still going on, the corresponding flags are still set, and interrupts and DMA requests are still being generated.

### 11.3.4 PWM Input Mode

The PWM input mode is used to measure the duty cycle and frequency of PWM and is a special case of the input capture mode. The operation is the same as input capture mode except for the following differences: PWM occupies two compare capture channels and the input polarity of the two channels is set to opposite, one of the signals is set as trigger input and SMS is set to reset mode.

For example, to measure the period and frequency of the PWM wave input from TI1, the following operations are required.

- 1) Set TI1 (TI1FP1) to be the input of IC1 signal. Set CC1S to 01b.
- 2) Set TI1FP1 to rising edge active. Holding CC1P at 0.
- 3) Set TI1 (TI1FP2) as the input of IC2 signal. Set CC2S to 10b.
- 4) Select TI1FP2 to set to falling edge active. Set CC2P to 1.
- 5) Select TI1FP1 as the source of the clock source. set TS to 101b.
- 6) Set the SMS to reset mode, i.e. 100b.
- 7) Enables input capture. CC1E and CC2E are set.

Thus the value of compare capture register 1 is the period of the PWM, and the value of compare capture register 2 is its duty cycle.

### 11.3.5 PWM Output Mode

PWM output mode is one of the basic functions of the timer. PWM output mode is most commonly used to determine the PWM frequency using the reload value and the duty cycle using the capture comparison register. Set 110b or 111b in the OCxM field to use PWM mode 1 or mode 2, set the OCxPE bit to enable the preload register, and finally set the ARPE bit to enable automatic reload of the preload register. Since the value of the preload register can only

be sent to the shadow register when an update event occurs, the UG bit needs to be set to initialize all registers before the core counter starts counting. In PWM mode, the core counter and the compare capture register are always comparing, and depending on the CMS bit, the timer is able to output edge-aligned or center-aligned PWM signals.

- Edge alignment

When edge alignment is used, the core counter is incremented or decremented, and in the PWM mode 1 scenario, OCxREF is high when the core counter value is greater than the compare capture register, and low when the core counter value is less than the compare capture register (e.g., when the core counter grows to the value of R16\_TIMx\_ATRLR and reverts to all zeros).

- Central alignment

When using the central alignment modes, the core counter runs in alternating incremental and decremental count modes, and OCxREF makes rising and falling jumps when the values of the core counter and the compare capture register match. However, the comparison flags are set at different times in the three central alignment modes. When using the central alignment modes, it is best to generate a software update flag (Set the UG bit) before starting the core counter.

### 11.3.6 Complementary Output and Dead-time Insertion

The compare/capture channel generally has two output pins (Compare/capture channel 4 has only one output pin) and can output two complementary signals (OCx and OCxN). OCx and OCxN can be independently set for polarity via the CCxP and CCxNP bits, independently set for output enable via CCxE and CCxNE, and independently set for output enable via the MOE, OIS, OISN, OSSI, and OSSR bits for dead-time and other controls. Enabling the OCx and OCxN outputs simultaneously will insert a dead-time, and each channel has a 10-bit dead-time generator. OCx and OCxN are generated by the OCxREF association. If both OCx and OCxN are high active, then OCx is the same as OCxREF except that the rising edge of OCx is equivalent to OCxREF with a delay, and OCxN is the opposite of OCxREF in that its rising edge will have a delay relative to the falling edge of the reference signal. If the delay is greater than the effective output width, the corresponding pulse will not be generated.

The relationship between OCx and OCxN and OCxREF is illustrated in Figure 10-4, which shows the dead-time.

Figure 11-4 Complementary outputs and dead-time

### 11.3.7 Brake Signal

When the brake signal is generated, the output enable signal and invalid level are modified according to the MOE, OIS, OISN, OSSI, and OSSR bits. However, OCx and OCxN will not be at the active level at any time. The source of the brake event can come from the brake input pin or it can be a clock failure event which is generated by the CSS (Clock Safety System).

After system reset, the brake function is disabled by default (MOE bit is low), and setting the BKE bit enables the brake function. The polarity of the input brake signal can be set by setting BKP, and the BKE and BKP signals can be written at the same time, and there is a delay of one HB clock before the actual writing, so you need to wait for one HB cycle to read the written value correctly.

At the presence of the selected level on the brake pin the system will generate the following actions.

- 1) The MOE bit is cleared asynchronously, setting the output to an invalid, idle or reset state, depending on the setting of the SOOI bit.
- 2) After the MOE has been cleared, each output channel outputs a level determined by OISx.
- 3) When using complementary outputs: the outputs are placed in a null state, depending on the polarity.
- 4) If the BIE is set, an interrupt is generated when the BIF is set; if the BDE bit is set, a DMA request is generated.
- 5) If the AOE is set, the MOE bit is automatically set at the next update event UEV.

### 11.3.8 Single Pulse Mode

Single pulse mode can be used to allow the microcontroller to respond to a specific event by causing it to generate a pulse after a delay, with the delay and width of the pulse programmable. Placing the OPM bit allows the core counter to stop when the next update event UEV is generated (Counter flips to 0).

As shown in Figure 11-5, a positive pulse of length  $T_{pulse}$  needs to be generated on OC1 after a delay  $T_{delay}$  at the beginning of a rising edge detected on the TI2 input pin.

Figure 11-5 Generation of single pulse

- 1) Set TI2 to trigger. Setting the CC2S field to 01b to map TI2FP2 to TI2; setting the CC2P bit to 0b to set TI2FP2 as rising edge detection; setting the TS field to 110b to set TI2FP2 as trigger source; setting the SMS field to 110b to set TI2FP2 to be used to start the counter.
- 2)  $T_{delay}$  is determined by the value of the Compare Capture Register, and  $T_{pulse}$  is determined by the value of the Auto Reload Value Register and the Compare Capture Register.

### 11.3.9 Encoder Mode

The encoder mode is a typical application of the timer and can be used to access the biphasic output of the encoder. The counting direction of the core counter is synchronized with the direction of the encoder's rotation axis, and each pulse output from the encoder will cause the core counter to add or subtract one. To use the encoder, set the SMS field to 001b (Count only on TI2 edge), 010b (Count only on TI1 edge) or 011b (Count on both TI1 and TI2 edges), connect the encoder to the input of comparison capture channels 1 and 2, and set a value for the reload value register, which can be set to a larger value. When in encoder mode, the internal compare/capture register, prescaler, repeat count register, etc. of the timer are working normally. The following table shows the relationship between the counting direction and the encoder signal.

Table 11-1 Relationship between counting direction and encoder signal of timer encoder mode

| Counting effective edges            | The level of relative signals | TI1FP1 signal edge |                   | TI2FP2 signal     |                   |
|-------------------------------------|-------------------------------|--------------------|-------------------|-------------------|-------------------|
|                                     |                               | Rising edge        | Falling edge      | Rising edge       | Falling edge      |
| Counting at TI1 edge only           | high                          | Downward counting  | Upward counting   | No count          |                   |
|                                     | low                           | Upward counting    | Downward counting |                   |                   |
| Counting at TI2 edge only           | high                          | No count           |                   | Upward counting   | Downward counting |
|                                     | low                           |                    |                   | Downward counting | Upward counting   |
| Double edge counting at TI1 and TI2 | high                          | Downward counting  | Upward counting   | Upward counting   | Downward counting |
|                                     | low                           | Upward counting    | Downward counting | Downward counting | Upward counting   |

### 11.3.10 Timer Synchronization Mode

Timers are capable of outputting clock pulses (TRGO) and receiving inputs from other timers (ITRx). The source of ITRx (TRGO from other timers) is different for different timers. The timer internal trigger connections are shown in Table 11-2.

Table 11-2 TIMx internal trigger connections

| Slave timer | ITR0 (TS=000) | ITR1 (TS=001) | ITR2 (TS=010) | ITR3 (TS=011) |
|-------------|---------------|---------------|---------------|---------------|
| TIM1        | -             | TIM2          | -             | -             |
| TIM2        | TIM1          | -             | -             | -             |

### 11.3.11 Debug Mode

When the system enters debug mode, the timer continues to run or stops according to the settings of the DBG module.

## 11.4 Register Description

Table 11-3 TIM1-related registers list

| Name               | Access address | Description                        | Reset value |
|--------------------|----------------|------------------------------------|-------------|
| R16_TIM1_CTLR1     | 0x40012C00     | Control Register 1                 | 0x0000      |
| R16_TIM1_CTLR2     | 0x40012C04     | Control Register 2                 | 0x0000      |
| R16_TIM1_SMCFR     | 0x40012C08     | Slave Mode Control Register        | 0x0000      |
| R16_TIM1_DMAINTENR | 0x40012C0C     | DMA/Interrupt Enable Register      | 0x0000      |
| R16_TIM1_INTFR     | 0x40012C10     | Interrupt Status Register          | 0x0000      |
| R16_TIM1_SWEVGR    | 0x40012C14     | Event Generation Register          | 0x0000      |
| R16_TIM1_CHCTLR1   | 0x40012C18     | Compare/Capture Control Register 1 | 0x0000      |

|                  |            |   |            |
|------------------|------------|---|------------|
| R16_TIM1_CHCTLR2 | 0x40012C1C | Compare/Capture Control Register 2      | 0x0000     |
| R16_TIM1_CCER    | 0x40012C20 | Compare/Capture Enable Register         | 0x0000     |
| R16_TIM1_CNT     | 0x40012C24 | Counter of Advanced-control Timer       | 0x0000     |
| R16_TIM1_PSC     | 0x40012C28 | Counting Clock Prescaler                | 0x0000     |

| 1 | CC1G | WO | Compare/capture event generation 1, generates compare/capture event 1.<br>This bit is set by software and zeroed by hardware. Used to generate a comparison capture event.<br>1: Generates a compare/capture event in compare/capture channel 1:<br>If compare/capture channel 1 is configured as output: Set CC1IF bit. If enable corresponding interrupt and DMA, it will generate corresponding interrupt and DMA;<br>If compare/capture channel 1 is configured as input: The current core counter' value is captured to compare/capture register 1; Set CC1IF bit, if enable corresponding interrupt and DMA, it will generate corresponding interrupt and DMA. If CC1IF is already set, set CC1OF bit.<br>0: No action. | G |
| 0 | UG   | WO | Updated event generation bit, generates event. The bit is set by software, cleared by hardware.<br>1: Initialize the counter and generate an update event;<br>0: No action.<br><i>Note: The counter of the prescaler is also cleared, but the prescaler coefficient remains the same. If the core counter is cleared in centrosymmetric mode or increment mode, the core counter takes the value of the value register if it is in subtractive mode.</i>  | 0 |

### 11.4.7 Compare/Capture Control Register 1 (TIM1\_CHCTLR1)

Offset address: 0x18

The channel can be used for input (Capture mode) or output (Compare mode), and the direction of the channel is defined by the corresponding CCxS bits. The functions of other bits of the register are different in input and output modes. OCxx describes the function of the channel in output mode, and ICxx describes the function of the channel in input mode.

|           |           |    |             |       |           |           |           |   |             |       |           |   |   |   |   |
|-----------|-----------|----|-------------|-------|-----------|-----------|-----------|---|-------------|-------|-----------|---|---|---|---|

Compare mode (Pin direction is output).

| Bit | Name | Access | Description | Reset value |
|-----|------|--------|-------------|-------------|
|-----|------|--------|-------------|-------------|

|         |           |    |  |   |
|---------|-----------|----|--|---|
| 15      | OC2CE     | RW | <p>Compare/capture channel 2 clear enable bit.</p> <p>1: Once the ETRF input high level is detected, clear the OC2REF bit zero.</p> <p>0: OC2REF is not affected by ETRF input.</p>  | 0 |
| [14:12] | OC2M[2:0] | RW | <p>Compare capture channel 2 mode settings fields.</p> <p>The three bits define the action of outputting the reference signal OC2REF, while OC2REF determines the values of OC2 and OC2N. OC2REF is efficient at high levels, while the effective levels for OC2 and OC2N depend on the CC2P and CC2NP bits.</p> <p>000: Frozen. The comparison between the value of the compare/capture register and the core counter has no effect on OC2REF;</p> <p>001: Force to be set to a valid level. Force OC2REF to be high when the core counter is the same as the value of compare/capture register 1;</p> <p>010: Force to be set to an invalid level. Force OC2REF to be low when the value of the core counter is the same as that of compare/capture register 1</p> <p>011: Flip. Flip the level of the OC2REF when the core counter is the same as the value of the compare/capture register 1;</p> <p>100: Force to be set to an invalid level. Force OC2REF to be low;</p> <p>101: Force to be set to a valid level. Force OC2REF to be high;</p> <p>110: PWM mode 1: When counting upward, once the core counter is greater than the value of the compare/capture register, channel 2 is an invalid level, otherwise it is an effective level; when counting down, once the core counter is greater than the value of the compare/capture register, channel 2 is an effective level, otherwise it is an invalid level;</p> <p>111: PWM mode 2: When counting upward, channel 2 is an effective level once the core counter is greater than the value of the compare/capture register, otherwise it is an invalid level; when counting down, once the core counter is greater than the value of the compare/capture register, channel 2 is an invalid level, otherwise it is an effective level (OC2REF=1).</p> <p><i>Note: Once the LOCK level is set to 3 and CC2S=00b, this bit cannot be modified. In PWM mode 1 or PWM mode 2, the OC2REF level changes only when the comparison result changes or when the output compare mode is switched from frozen mode to PWM mode.</i></p> | 0 |

|       |           |    |   |   |
|-------|-----------|----|---|---|
| 11    | OC2PE     | RW | <p>Compare capture register 2 preload enable bit.</p> <p>1: Enable preload function of the compare/capture register 2. The read and write operation only operates on the preload register. The preload value of the compare/capture register 2 is loaded into the current shadow register when the update event arrives.</p> <p>0: Disable preload function of the compare/capture register 2. Compare/capture register 2 can be written at any time and the newly written value takes effect immediately.</p> <p><i>Note: Once the LOCK level is set to 3 and CC2S=00, this bit cannot be modified; only in mono-pulse mode (OPM=1) you can use PWM mode without confirming the preload register, otherwise its action is uncertain.</i></p>   | 0 |
| 10    | OC2FE     | RW | <p>Compare/capture channel 2 fast enable level. This bit is used to speed up the compare/capture channel of the response of output to triggered input events.</p> <p>1: The input to the valid edge of the trigger acts as if a comparison match had occurred. Therefore, the OC is set to the comparison level independent of the comparison result. The delay between the effective edge of the sampling trigger and the output of the compare/capture channel 2 is shortened to three clock cycles;</p> <p>0: According to the value of the counter and the compare capture register 1, compare/capture channel 2 operate normally, even if the trigger is turned on. When the input of the flip-flop has a valid edge, the minimum delay of activating the output of the compare/capture channel 2 is 5 clock cycles.</p> <p><i>Note: OC2FE works only if the channel is configured in PWM1 or PWM2 mode.</i></p> | 0 |
| [9:8] | CC2S[1:0] | RW | <p>Compare/capture channel 2 input selection fields.</p> <p>00: Compare/capture channel 2 is configured to output;</p> <p>01: Compare/capture channel 2 is configured as input and IC2 is mapped on TI2;</p> <p>10: Compare/capture channel 2 is configured as input and IC2 is mapped on TI1;</p> <p>11: Compare/capture channel 2 is configured as input and IC2 is mapped on TRC. This mode works only when the internal trigger input is selected (selected by the TS bit).</p> <p><i>Note: Compare/capture channel 2 is writable only when the channel is closed (CC2E is 00:00).</i></p>  | 0 |
| 7     | OC1CE     | RW | Compare/capture channel 1 clear enable bit.   | 0 |

| [3:2] | IC1PSC[1:0] | RW | Compare/capture channel 1 prescaler configuration domain.  | 0 |
| [1:0] | CC1S[1:0]   | RW | Compare/capture channel 1 input selection domain.  | 0 |

### 11.4.8 Compare/Capture Control Register 2 (TIM1\_CHCTLR2)

Offset address: 0x1C

The channel can be used for input (Capture mode) or output (Compare mode), and the direction of the channel is defined by the corresponding CCxS bits. The functions of other bits of the register are different in input and output modes. OCxx describes the function of the channel in output mode, and ICxx describes the function of the channel in input mode.

## Chapter 12 General-purpose Timer (GPTM)

*The module described in this chapter is suitable for the full range of CH32V00X microcontrollers.*

The general-purpose timer module contains a 16-bit timer TIM2 that can be reinstalled automatically, which is used to measure the pulse width or generate pulses and PWM waves of a specific frequency. It can be used in automatic control, power supply and other fields.

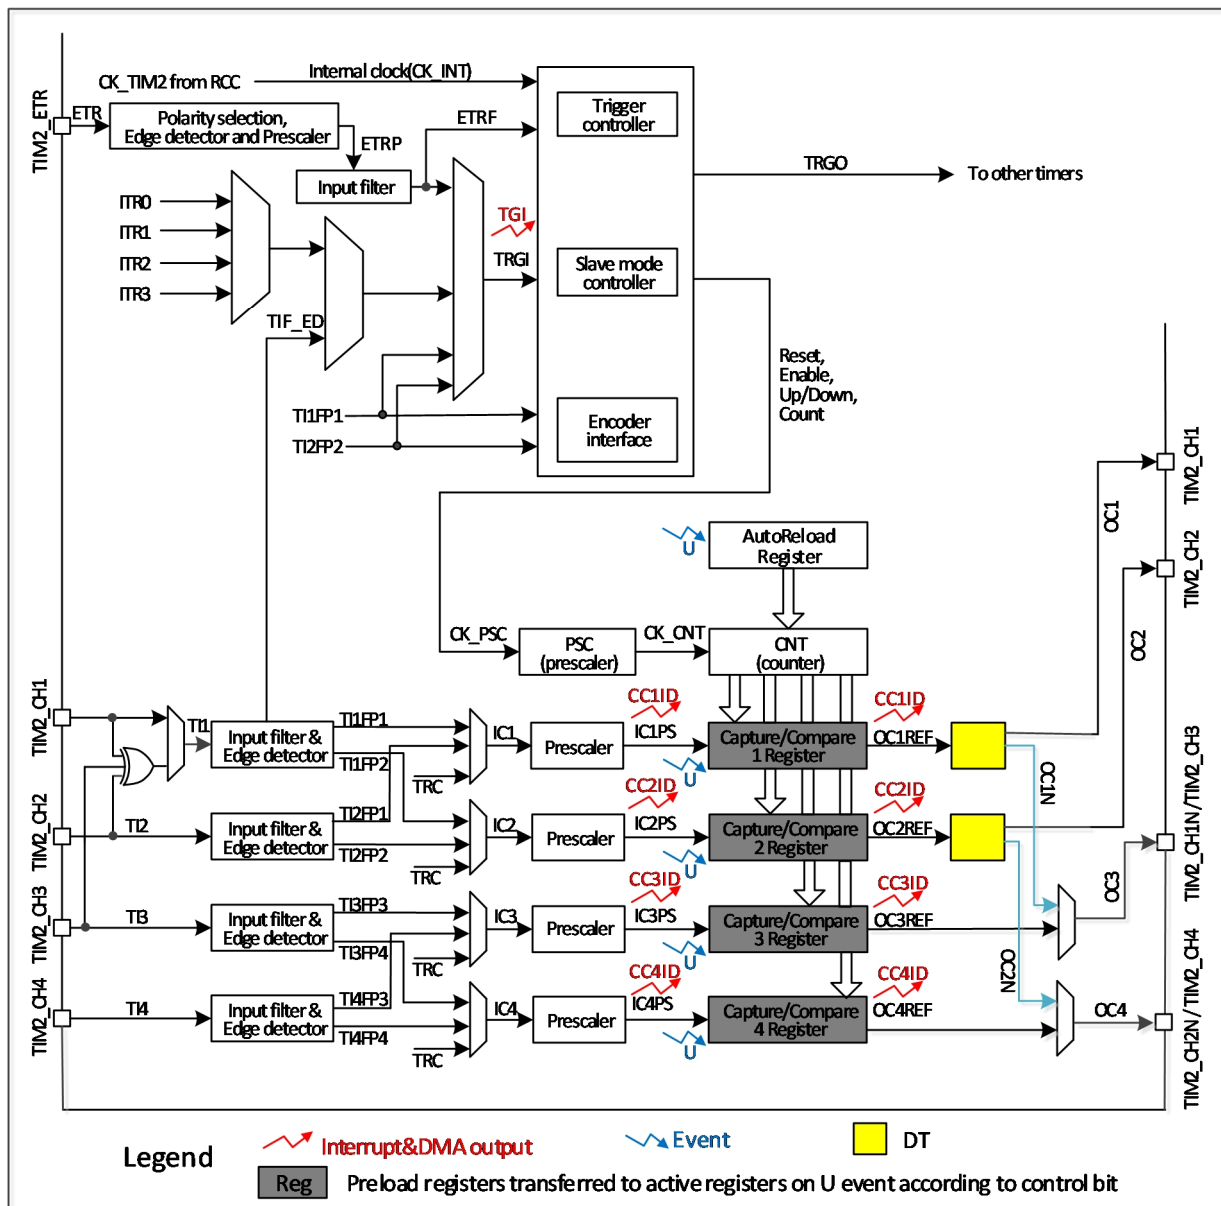

### 12.1 Main Features

The main features of the general-purpose timer include.

- 16-bit auto-reload counter, supports incremental counting mode, decremental counting mode and incremental and decremental counting mode
- 16-bit prescaler with dynamically adjustable crossover factor from 1 to 65536
- Support four independent comparison capture channels
- Each comparison capture channel supports multiple operating modes, such as: input capture, output comparison, PWM generation, and single pulse output
- Support external signal control timer
- Support DMA in multiple modes
- Support incremental coding, cascading and synchronization between timers

## 12.2 Principle and Structure

Figure 12-1 Block diagram of the structure of the general-purpose timer

### 12.2.1 Overview

As shown in Figure 12-1, the structure of the general-purpose timer can be roughly divided into three parts, namely the input clock part, the core counter part and the compare/capture channel part.

The clock of the general-purpose timer can come from the HB bus clock (CK\_INT), from the external clock input pin (TIM2\_ETR), from other timers with clock output function (ITRx), or from the input of the compare/capture channel (TIM2\_CHx). After various set filtering and frequency division operations, these input clock signals become CK\_PSC clocks and output to the core counter. In addition, these complex clock sources can also be output as TRGO to other timers and ADC peripherals.

The core of the general-purpose timer is a 16-bit counter (CNT). After the CK\_PSC is divided by the prescaler (PSC), the CK\_CNT is finally output to the CNT, CNT to support the increasing counting mode, the decreasing

counting mode and the increasing or decreasing counting mode, and there is an automatic reload value register (ATRLR) to reload the initialization values for the CNT at the end of each counting cycle.

The general-purpose timer has four sets of compare/capture channels, each of which can input pulses from exclusive pins or output waveforms to pins, i.e., the compare/capture channels support both input and output modes. The input of each channel of the compare/capture register supports filtering, dividing, edge detection, and other operations, and supports mutual triggering between channels, and can also provide clock for the core counter CNT. Each compare/capture channel has a set of compare/capture registers (CHxCVR) that support comparison with the main counter (CNT) to output pulses.

### 12.2.2 Difference between General-purpose Timer and Advanced-control Timer

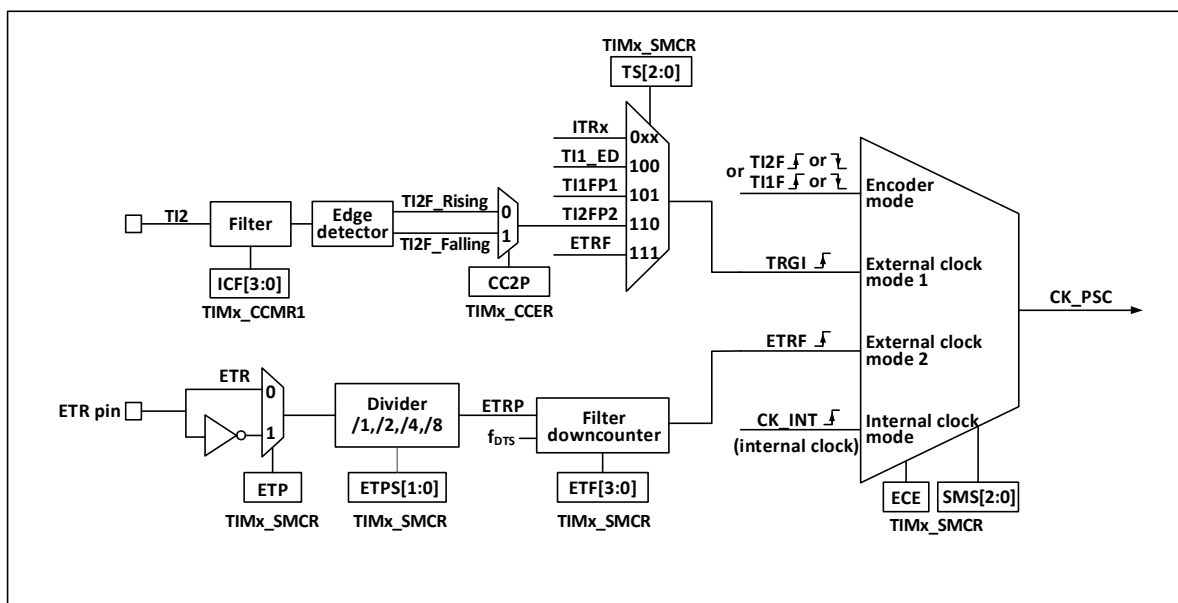

Compared to advanced-control timers, general purpose timers lack the following features.

- 1) The general-purpose timer lacks a repeat count register for counting the count cycles of the core counter.
- 2) The compare/capture channel of the general-purpose timer lacks dead-time generation and has no complementary output.
- 3) The general-purpose timer does not have a brake signal mechanism.

### 12.2.3 Clock Input

This section discusses the source of CK\_PSC. The clock source portion of the overall block diagram of the general-purpose timer is captured here.

Figure 12-2 General-purpose Timer CK\_PSC Source Block Diagram

The optional input clocks can be divided into 4 categories.

- 1) Route of the external clock pin (ETR) input: ETR → ETRP → ETRF.
- 2) Internal HB clock input route: CK\_INT.
- 3) Route from the comparison capture channel pin (TIM2\_CHx): TIMx\_CHx → TIx → TIxFPx, this route is also used in encoder mode.
- 4) Input from other internal timers: ITRx.

The actual operation can be divided into 3 categories by determining the choice of input pulse for the SMS of the

CK\_PSC source.

- 1) Selection of the internal clock source (CK\_INT).
- 2) External clock source mode 1.
- 3) External clock source mode 2.
- 4) Encoder mode.

All 4 clock source sources mentioned above can be selected by these 4 operations.

#### 12.2.3.1 Internal Clock Source (CK\_INT)

If the general-purpose timer is started when the SMS field is held at 000b, then it is the internal clock source (CK\_INT) that is selected as the clock. At this point CK\_INT is CK\_PSC.

#### 12.2.3.2 External Clock Source Mode 1

When the SMS domain is set to 111b, external clock source mode 1 is enabled. When external clock source 1 is enabled, TRGI is selected as the source for CK\_PSC. it is worth noting that the user also needs to select the source for TRGI by configuring the TS domain. the TS domain can select the following types of pulses as clock sources.

- 1) Internal trigger (ITRx, x is 0,1,2,3).
- 2) The signal after compare/capture channel 1 through the edge detector (TI1F\_ED).
- 3) Signals TI1FP1, TI2FP2 of the compare/capture channel.
- 4) The signal ETRF from the external clock pin input.

#### 12.2.3.3 External Clock Source Mode 2

Use external trigger mode 2 to count on every rising or falling edge of the external clock pin input. When the ECE position is set, the external clock source mode 2 is used. when using the external clock source mode 2, ETRF is selected as CK\_PSC. the ETR pin becomes ETRP after passing through the optional inverter (ETP), divider (ETPS), and then ETRF after passing through the filter (ETF).

With the ECE position bit and the SMS set to 111b, then it is equivalent to the TS selecting ETRF as the input.

#### 12.2.3.4 Encoder Mode

Setting the SMS to 001b, 010b, 011b will enable the encoder mode. Enabling encoder mode allows you to select a specific level in TI1FP1 and TI2FP2 to signal the output with another jump edge as the signal. This mode is used when an external encoder is used. Refer to Section 12.3.7 for specific functions.

### 12.2.4 Counters and Peripherals

The CK\_PSC is input to the prescaler (PSC) for frequency division. PSC is 16-bit, and the actual frequency division coefficient is equivalent to the value of R16\_TIM2\_PSC + 1. CK\_PSC becomes CK\_INT after PSC. Changing the value of R16\_TIM1\_PSC does not take effect in real time, but is updated to PSC after the update event. Update events include UG bit zeroing and reset.

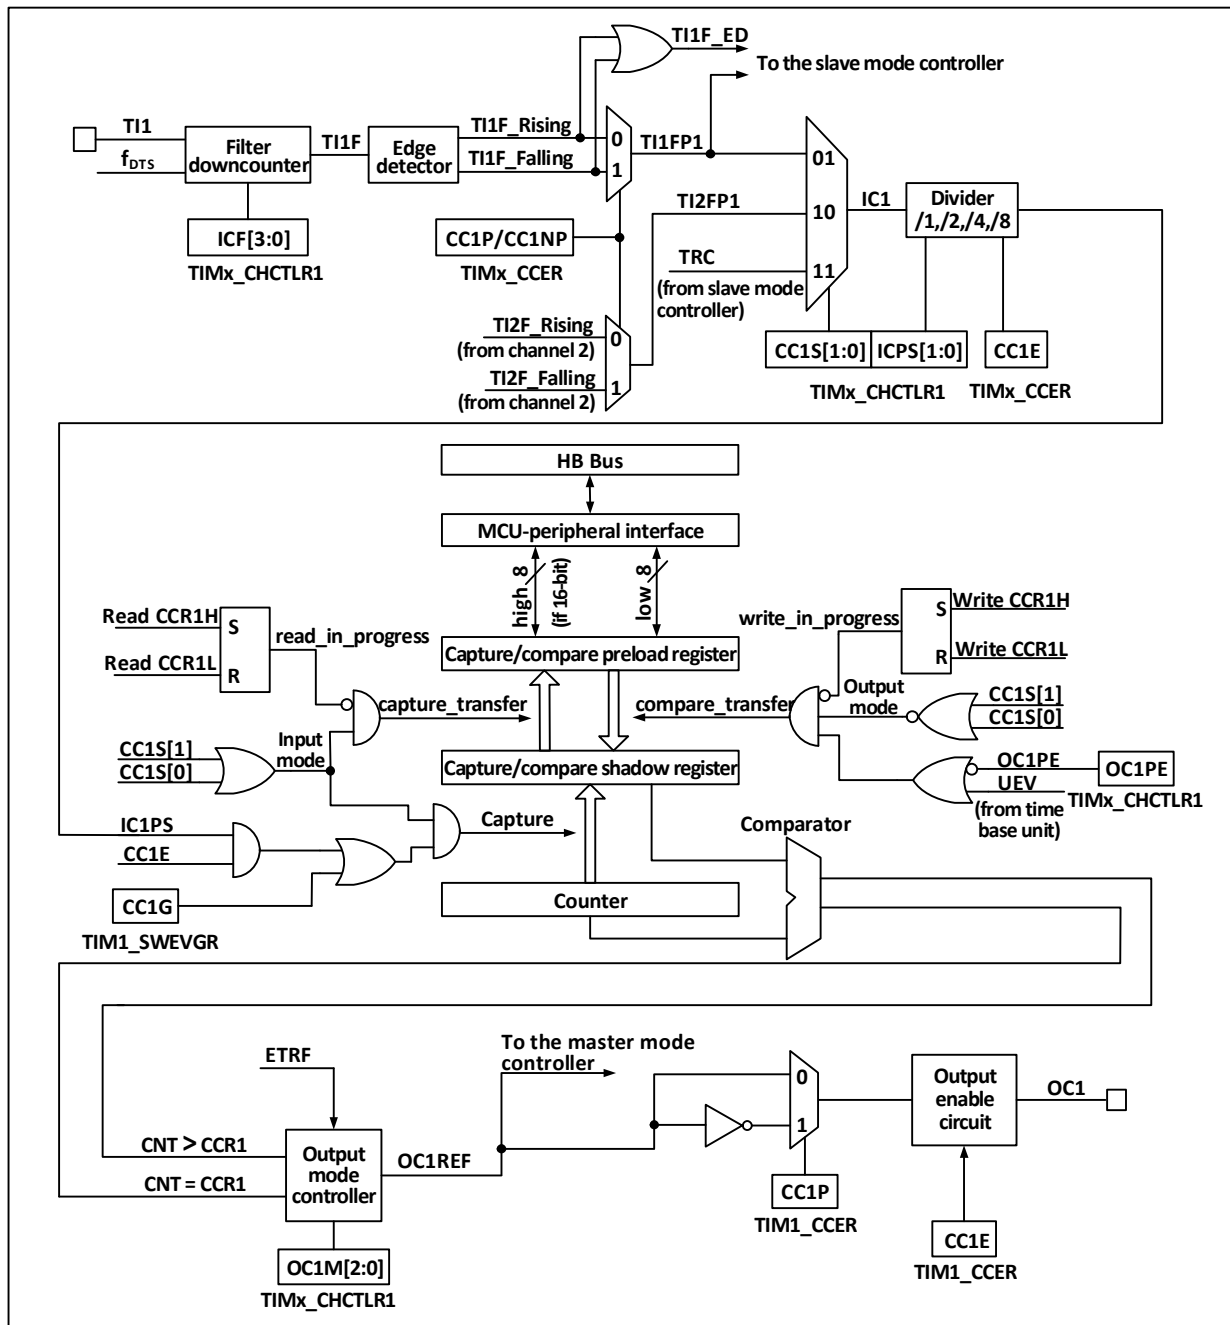

The core of the timer is a 16-bit counter (CNT). The CK\_CNT will eventually be entered into the CNT, CNT to support the increase count mode, the decrease count mode, and the increase and decrease count mode, and there is an automatic reload value register (ATRLR) to reload the initial values for the CNT at the end of each count cycle.

### 12.2.5 Compare/Capture Channels

The core of the compare/capture channel, which is the core of the timer to achieve complex functions, is the compare/capture register, supplemented by digital filtering, frequency division and inter-channel multiplexing in

the peripheral input section, and comparator and output control in the output section. The structure block diagram of the compare/capture channel is shown in Figure 12-3.

Figure 12-3 Block diagram of the structure of the compare/capture channel

Signal input from the channel x pin can be selected as TIx (the source of TI1 can be more than just CH1, see timer block figure 121), TI1 through the filter (ICF [3:0]) to generate TI1F, and then after the edge detector is divided into TI1F\_Rising and TI1F\_Falling, the two signals after selection (CC1P) generated TI1FP1, TI1FP1 and TI2FP1 from channel 2 together to the CC1S to choose to become IC1, after ICPS frequency division to be sent to the comparison capture register.

The compare/capture register consists of a preload register and a shadow register, and the read and write process operates only the preload register. In capture mode, capture occurs on the shadow register and then copied to the preload register; in compare mode, the contents of the preload register are copied to the shadow register, and then the contents of the shadow register are compared with the core counter (CNT).

## 12.3 Function and Implementation

The complex functions of a general-purpose timer are implemented by manipulating the timer's compare/capture channel, clock input circuitry, and counter and peripheral components. The clock input to the timer can be derived from multiple clock sources including the input to the compare capture channel. The operation of the compare/capture host channel and clock source selection directly determines its function. The compare/capture channel is bidirectional and can operate in both input and output modes.

### 12.3.1 Input Capture Mode

The input capture mode is one of the basic functions of the timer. The principle of input capture mode is that when a determined edge on the ICxPS signal is detected, a capture event is generated and the current value of the counter is latched into the compare capture register (R16\_TIM2\_CHCTLRx). The CCxIF (in R16\_TIM2\_INTFR) is set when a capture event occurs, and the corresponding interrupt or DMA is generated if enabled. If the CCxIF is already set when a capture event occurs, the CCxOF bit is set. the CCxIF can be cleared by software, or by hardware by reading the compare/capture register. CCxOF is cleared by software.

An example of channel 1 to illustrate the steps to use the input capture mode is as follows.

- 1) Configure the CCxS domain to select the source of the ICx signal. For example, set it to 10b and select TI1FP1 as the source of IC1, not using the default setting, the CCxS domain defaults to making the comparison capture module the output channel.
- 2) Configure the ICxF domain to set the digital filter for the TI signal. The digital filter will sample the signal at a determined frequency, a determined number of times, and then output a hop. This sampling frequency and number of times is determined by ICxF.
- 3) Configure the CCxP bit to set the polarity of the TIxFPx. For example, keeping the CC1P bit low and selecting rising edge jumps.
- 4) Configure the ICxPS domain to set the ICx signal to be the crossover factor between ICxPS. For example, keeping ICxPS at 00b, without crossover.
- 5) Configure the CCxE bit to allow capturing the value of the core counter (CNT) into the compare capture register. Set the CC1E bit.
- 6) Configure the CCxIE and CCxDE bits as needed to determine whether to allow enable interrupts or DMA.

This completes the compare/capture channel configuration.

When a captured pulse is input to TI1, the value of the core counter (CNT) is recorded in the compare/capture register, CC1IF is set, and the CCIOF bit is set when CC1IF has been set before. If the CC1IE bit is set, then an interrupt is generated; if CC1DE is set, a DMA request is generated. An input capture event can be generated by software by way of writing the event generation register (R16\_TIM2\_SWEVGR).

### 12.3.2 Compare Output Mode

The compare output mode is one of the basic functions of the timer. The principle of the compare output mode is to output a specific change or waveform when the value of the core counter (CNT) agrees with the value of the compare/capture register. the OCxM field (in R16\_TIMx\_CHCTLRx) and the CCxP bit (in R16\_TIMx\_CCER) determine whether the output is a definite high or low level or a level flip. The CCxIF bit is also set when a compare coherent event is generated. If the CCxIE bit is pre-set, an interrupt will be generated; if the CCxDE bit is pre-set, a DMA request will be generated.

To configure to compare output modes, proceed as follows.

- 1) Configuring the clock source and auto-reload value of the core counter (CNT).

- 2) Set the count value to be compared to the compare/capture register (R16\_TIM2\_CHxCVR).
- 3) Set the CCxIE bit if an interrupt needs to be generated.
- 4) Keep OCxPE at 0 to disable the preload register for the compare/capture register.
- 5) Setting the output mode, setting the OCxM field and the CCxP bit.
- 6) Enable the output, setting the CCxE bit.
- 7) Setting the CEN bit to start the timer.

### 12.3.3 Forced Output Mode

The output pattern of the timer's compare capture channel can be forced by software to output a determined level without relying on comparison of the compare capture register's shadow register with the core counter.

This is done by setting OCxM to 100b, which forces OCxREF to low, or by setting OCxM to 101b, which forces OCxREF to high.

Note that by forcing OCxM to 100b or 101b, the comparison process between the internal main counter and the compare capture register is still going on, the corresponding flags are still set, and interrupts and DMA requests are still being generated.

### 12.3.4 PWM Input Mode

The PWM input mode is used to measure the duty cycle and frequency of PWM and is a special case of the input capture mode. The operation is the same as input capture mode except for the following differences: PWM occupies two compare/capture channels and the input polarity of the two channels is set to opposite, one of the signals is set as trigger input and SMS is set to reset mode.

For example, to measure the period and frequency of the PWM wave input from TI1, the following operations are required.

- 1) Set TI1 (TI1FP1) to be the input of IC1 signal. Set CC1S to 01b.
- 2) Set TI1FP1 to rising edge active. Holding CC1P at 0.
- 3) Set TI1 (TI1FP2) as the input of IC2 signal. Set CC2S to 10b.
- 4) Select TI1FP2 to set to falling edge active. Set CC2P to 1.
- 5) Select TI1FP1 as the source of the clock source. set TS to 101b.
- 6) Set the SMS to reset mode, i.e. 100b.
- 7) Enable input capture. CC1E and CC2E are set.

### 12.3.5 PWM Output Mode

PWM output mode is one of the basic functions of the timer. PWM output mode is most commonly used to determine the PWM frequency using the reload value and the duty cycle using the compare/capture register. Set 110b or 111b in the OCxM field to use PWM mode 1 or mode 2, set the OCxPE bit to enable the preload register, and finally set the ARPE bit to enable the automatic reload of the preload register. The value of the preload register can only be sent to the shadow register when an update event occurs, so the UG bit needs to be set to initialize all registers before the core counter starts counting. In PWM mode, the core counter and the compare/capture register are always comparing, and depending on the CMS bit, the timer is able to output edge-aligned or center-aligned PWM signals.

#### ● Edge alignment

When using edge alignment, the core counter is incremented or decremented, and in the PWM mode 1 scenario, OCxREF rises to high when the core counter value is greater than the compare/capture register; when the core counter value is less than the compare/capture register (For example, when the core counter grows to the value of R16\_TIM2\_ATRLR and reverts to full 0), OCxREF falls to low.

- Central alignment

When using the central alignment modes, the core counter runs in alternating incremental and decremental count modes, and OCxREF performs rising and falling jumps when the values of the core counter and the compare/capture register match. However, the comparison flags are set at different times in the three central alignment modes. When using the central alignment modes, it is best to generate a software update flag (set the UG bit) before starting the core counter.

### 12.3.6 Single Pulse Mode

The single pulse mode can respond to a specific event by generating a pulse after a delay, with programmable delay and pulse width. Setting the OPM bit stops the core counter when the next update event UEV is generated (counter flips to 0).

Figure 12-4 Event generation and impulse response

As shown in Figure 12-4, a positive pulse of length  $T_{\text{pulse}}$  needs to be generated on OC1 after a delay  $T_{\text{delay}}$  at the beginning of a rising edge detected on the TI2 input pin.

- 1) Set TI2 to trigger. Setting the CC2S field to 01b to map TI2FP2 to TI2; setting the CC2P bit to 0b to set TI2FP2 as rising edge detection; setting the TS field to 110b to set TI2FP2 as trigger source; setting the SMS field to 110b to set TI2FP2 to be used to start the counter.
- 2)  $T_{\text{delay}}$  is defined by the Compare/Capture Register and  $T_{\text{pulse}}$  is determined by the value of the Auto Reload Value Register and the Compare/Capture Register.

### 12.3.7 Encoder Mode

The encoder mode is a typical application of the timer and can be used to access the biphasic output of the encoder. The counting direction of the core counter is synchronized with the direction of the encoder's rotation axis, and each pulse output from the encoder will add or subtract one from the core counter. To use the encoder, set the SMS field to 001b (count only on TI2 edge), 010b (count only on TI1 edge) or 011b (count on both TI1 and TI2 edges), connect the encoder to the input of the compare/capture channels 1 and 2, and set a reload value counter value, which can be set to a larger value. When in encoder mode, the internal compare/capture register, prescaler, repeat count register, etc. of the timer are working normally. The following table shows the relationship between the counting direction and the encoder signal.

Table 12-1 Relationship between counting direction and encoder signal of timer encoder mode

| Counting effective edges            | The level of relative signals | TI1FP1 signal edge |                   | TI2FP2 signal edge |                   |
|-------------------------------------|-------------------------------|--------------------|-------------------|--------------------|-------------------|
|                                     |                               | Rising edge        | Falling edge      | Rising edge        | Falling edge      |
| Counting at TI1 edge only           | High                          | Downward counting  | Upward counting   | No count           |                   |
|                                     | Low                           | Upward counting    | Downward counting |                    |                   |
| Counting at TI2 edge only           | High                          | No count           |                   | Upward counting    | Downward counting |
|                                     | Low                           |                    |                   | Downward counting  | Upward counting   |
| Double edge counting at TI1 and TI2 | High                          | Downward counting  | Upward counting   | Upward counting    | Downward counting |
|                                     | Low                           | Upward counting    | Downward counting | Downward counting  | Upward counting   |

### 12.3.8 Timer Synchronization Mode

Timers are capable of outputting clock pulses (TRGO) and also receiving inputs from other timers (ITRx). The source of ITRx (TRGO from other timers) is different for different timers. The timer internal trigger connections are shown in Table 11-2.

Table 12-2 GTPM internal trigger connection

| Slave timer | ITR0 (TS=000) | ITR1 (TS=001) | ITR2 (TS=010) | ITR3 (TS=011) |
|-------------|---------------|---------------|---------------|---------------|
| TIM2        | TIM1          | -             | -             | -             |
| TIM1        | -             | TIM2          | -             | -             |

### 12.3.9 Debug Mode

When the system enters the debug mode, the timer can be controlled to continue running or stop according to the setting of DBG module.

## 12.4 Register Description

Table 12-3 TIM2-related registers list

| Name               | Offset address | Description                        | Reset value |
|--------------------|----------------|------------------------------------|-------------|
| R16_TIM2_CTLR1     | 0x40000000     | Control Register 1                 | 0x0000      |

### 12.4.7 Compare/Capture Control Register 1 (TIM2\_CHCTLR1)

Offset address: 0x18

The channel can be used for input (Capture mode) or output (Compare mode), and the direction of the channel is defined by the corresponding CCxS bits. The functions of other bits of the register are different in input and output modes. OCxx describes the function of the channel in output mode, and ICxx describes the function of the channel in input mode.

## Chapter 13 Streamlined Timer (SLTM)

The module description in this chapter applies only to CH32V006, CH32V007, and CH32M007 products.

The Streamlined Timer module contains a 16-bit timer TIM3 that can be reinstalled automatically, which is used to generate pulses of a specific frequency (non-output) with TIM1 and ADC modules.

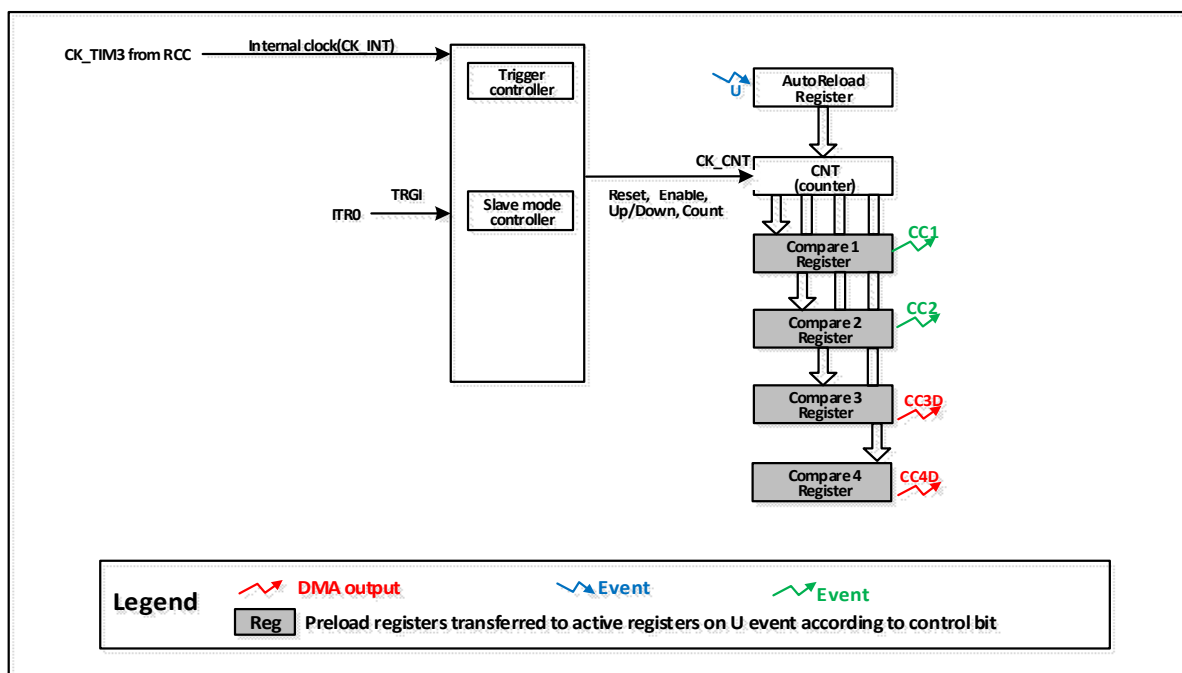

### 13.1 Main Features

The main features of the streamlined timer include:

- 16-bit auto-reload counter, supports incremental counting mode, decremental counting mode, incremental and decremental counting mode
- Support 4 independent compare channels, only support output comparison
- Support cascade synchronization with TIM1.
- Support for using DMA

### 13.2 Principle and Structure

Figure 13-1 Block diagram of the structure of the streamlined timer

#### 13.2.1 Overview

As shown in Figure 13-1, the structure of the streamlined timer can be roughly divided into three parts, namely the input clock part, the core counter part and the compare channel part.

The clock of the streamlined timer can come from the HB bus clock (CK\_INT) and from other timers (ITR1) with clock output function. After the set filtering operation, these input clock signals become CK\_PSC clocks and output to the core counter.

The core of the streamlined timer is a 16-bit counter (CNT). CK\_PSC input directly to CNT, CNT without frequency division supports incremental counting mode, decremental counting mode and incremental or decremental counting

mode, and has an automatic reload value register (ATRLR) to reload initialization values for CNT at the end of each counting cycle.

The streamlined timer has four sets of compare channels, each of which has a set of compare registers (CHxCVR). Channels 1 and 2 support comparison with the master counter (CNT) and output pulses, that is, only the output mode; channels 3 and 4 support the comparison of the main counter (CNT) to generate DMA requests.

### 13.2.2 Clock Input

This section discusses the source of CK\_PSC. The clock source part of the overall structure block diagram of the streamlined timer is intercepted here.

Figure 13-2 Streamlined timer CK\_PSC source block diagram

The optional input clocks can be divided into 2 categories.

- 1) Internal HB clock input route: CK\_INT
- 2) Input from other internal timers: ITRx.

By determining the input pulse selection of the SMS from which the CK\_PSC comes from, the actual operation can be divided into two categories:

- 1) Select internal clock source (CK\_INT)
- 2) External clock source mode 1

The two clock sources mentioned above can be selected by these two operations.

#### 13.2.2.1 Internal Clock Source (CK\_INT)

If the compact timer is started when the SMS domain is kept at 000b, the internal clock source (CK\_INT) is selected as the clock. At this point, CK\_INT is CK\_PSC.

#### 13.2.2.2 External Clock Source Mode 1

If the SMS domain is set to 111b, external clock source mode 1 is enabled. When the external clock source 1 is enabled, the source from which TRGI is selected as the CK\_PSC is the internally triggered ITR1.

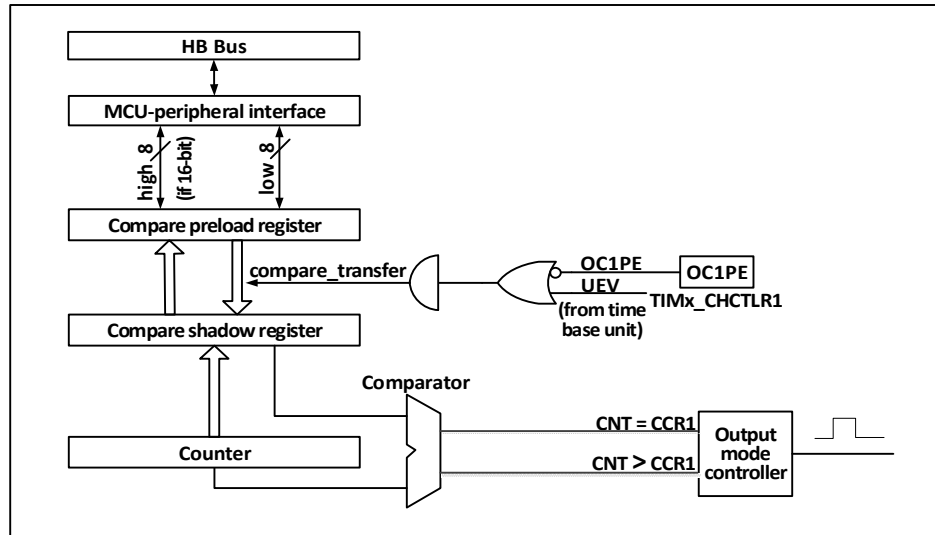

### 13.2.3 Counters and Peripherals

CK\_PSC is directly CK\_INT without frequency division. Reduced timer no counting clock pre-division function.

### 13.2.4 Compare Channel

The compare channel is the core of the timer to achieve complex functions, and its core is the compare register, supplemented by the output comparator. The structural block diagram of the compare channel is shown in figure 13-3.

Figure 13-3 Block diagram of the structure of the compare channel

The compare register consists of a preload register and a shadow register, and the read and write process operates only the preload register. During comparison, the contents of the preloaded register are copied to the shadow register, and then the contents of the shadow register are compared with the core counter (CNT).

## 13.3 Function and Implementation

The complex functions of the streamlined timer are realized by operating the compare channel of the timer, the clock input circuit, the counter and the surrounding components. The clock input of the timer may come from two clock sources including an internal clock source and trigger inputs of other timers. The operation of comparing the register channel and the clock source directly determines its function. The compare channel is unidirectional and only works in output mode.

### 13.3.1 Compare Output Mode

Compare output mode is one of the basic functions of timer. The principle of the compare output mode is that when the value of the core counter (CNT) is consistent with the value of the compare register, channel 1 ~ 2 outputs a specific waveform. Channel 3pr 4 generates a DMA request if the CCxDE bit is set in advance when a relatively consistent event is generated.

The steps to configure to compare output modes are as follows:

- 1) Configure the clock source and automatic reload values of the core counter (CNT)
- 2) Set the count value to be compared to the compare register (R16\_TIMx\_CHxCVR)
- 3) Keep OCxPE to 0 and disable preloaded registers that compare the obtained registers
- 4) Set the CEN bit to start the timer.

### 13.3.2 PWM Output Mode

PWM output mode is one of the basic functions of timer. The most common method of PWM output mode is to determine the PWM frequency using reinstalled values and to determine the duty cycle using comparison registers.

Set the OCxPE bit to enable the preloading register, and finally set the ARPE bit to enable the automatic reloading of the preloading register. When an update event occurs, the value of the preloaded register can be sent to the shadow register. In PWM mode, the core counter and the compare register are compared all the time, and according to the CMS bit, the timer can output edge-aligned or center-aligned PWM signals.

#### 1) Edge alignment

When edge alignment is used, the core counter increases or decreases, OCxREF rises to high when the value of the core counter is greater than the compare register, and OCxREF decreases to low when the value of the core counter is smaller than the compare register.

#### 2) Central alignment

When using the central alignment modes, the core counter runs in alternating incremental and decremental count modes, and OCxREF performs rising and falling jumps when the values of the core counter and the compare register match. However, the comparison flags are set at different times in the three central alignment modes.

### 13.3.3 Timer Synchronization Mode

The timer can only receive input from timer 1 (ITRx). The connection is triggered inside the timer as shown in Table 13-1.

Table 13-1 GTPM internal trigger connection

| Slave timer | ITR0 (TS=000) | ITR1 (TS=001) | ITR2 (TS=010) | ITR3 (TS=011) |
|-------------|---------------|---------------|---------------|---------------|
| TIM3        | TIM1          | -             | -             | -             |

### 13.3.4 Debug Mode

When the system enters the debug mode, the timer can be controlled to continue running or stop according to the setting of DBG module.

## 13.4 Register Description

Table 13-2 TIM3-related registers list

# Chapter 14 Universal Synchronous Asynchronous Receiver Transmitter (USART)

*This chapter USART1 module description applies to the full range of CH32V00X products; this chapter USART2 module description applies only to CH32V005, CH32V006, CH32V007 and CH32M007 products.*

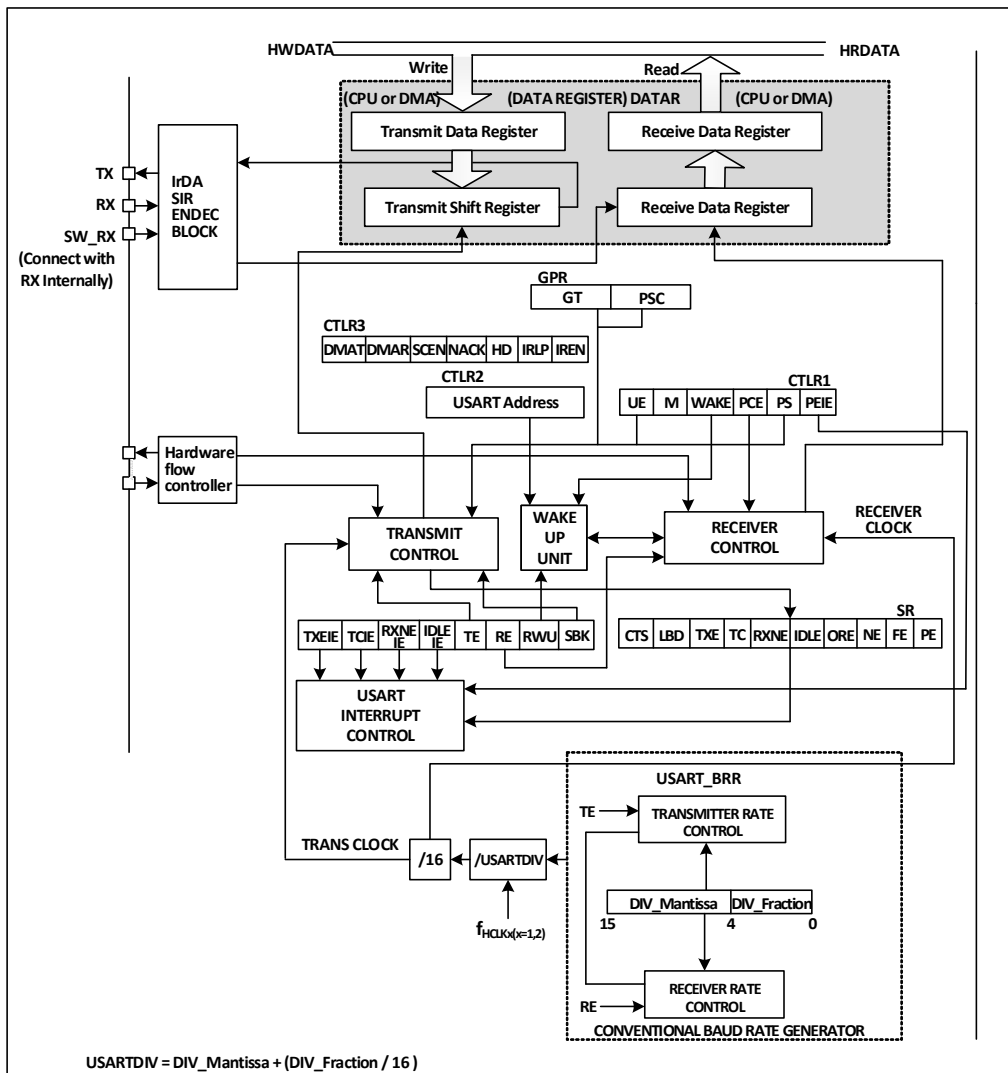

The module contains two general asynchronous transceivers USART1 and USART2.

## 14.1 Main Features

- Full-duplex or half-duplex synchronous or asynchronous communication
- NRZ data format
- Fractional baud rate generator, up to 3Mbps
- Programmable data length
- Configurable stop bits
- Support LIN, IrDA encoders, smart cards
- DMA support
- Multiple interrupt sources

## 14.2 Overview

Figure 14-1 Block diagram of synchronous/asynchronous transceiver

When the TE (transmit enable bit) is set, the data in the transmit shift register is output on the TX pin. When transmitting, the least significant bits are removed first, and each data frame starts with a low-level start bit, and then the transmitter sends eight-or nine-bit data words according to the setting on the M (word length) bit, and finally the number of configurable stop bits. If there is a parity bit, the last bit of the data word is the parity bit. After the TE is set, an idle frame is sent, which is 10-or 11-bit high, including the stop bit. The break frame is 10-or 11-bit low, followed by the stop bit.

## 14.3 Baud Rate Generator

The baud rate of the transceiver =  $HCLK / (16 * USARTDIV)$ , and HCLK is the clock of HB. The value of USARTDIV is determined based on the fields DIV\_M and DIV\_F in USART\_BRR. The formula for calculation is:

$$USARTDIV = DIV\_M + (DIV\_F/16)$$

It should be noted that the bit rate generated by the baud rate generator may not exactly generate the baud rate required by the user, which may be biased. In addition to taking as close a value as possible, the way to reduce the deviation can also be to increase the HB clock. For example, when the baud rate is set to 115200bps, the USARTDIV

value is set to 39.0625, and you can get exactly the baud rate of 115200bps at the highest frequency, but if you need the baud rate of 921600bps, the calculated USARTDIV is 4.88, but in fact, the value filled in USART\_BRR is only 4.875, the actual baud rate is 923076bps, with an error of 0.16%.

When the serial port waveform sent by the sender is transmitted to the receiver, the baud rate of the receiver and the sender has a certain error. The error mainly comes from three aspects: the actual baud rate of the receiver and the sender is different; the clock of the receiver and the sender has an error; the waveform changes in the line. The receiver of the peripheral module has a certain ability to receive tolerance. when the sum of the total deviation of the above three aspects is less than the tolerance limit of the module, the total deviation does not affect the transceiver. The tolerance limit of the module is affected by the use of fractional baud rate and M-bit (data field word length). The use of fractional baud rate and the use of 9-bit data field length will reduce the tolerance limit, but not less than 3%.

## 14.4 1-wire Half-duplex Mode

Half-duplex mode supports the use of a single pin (Using only TX pins) to receive and transmit, with TX pins and RX pins connected inside the chip.

The way to turn on half-duplex mode is to turn on the HDSEL position bit of control register 3 (R32\_USARTx\_CTLR3), but at the same time you need to turn off LIN mode and infrared mode, that is, to ensure that the IREN bit is reset, which is in control register 3 (R32\_USARTx\_CTLR3).

After setting it to half-duplex mode, you need to set the IO port of TX to multiplexing output high mode. In the case of TE setting, as long as the data is written to the data register, it will be sent. In particular, half-duplex mode may cause bus conflicts when multiple devices use single-bus transceiver, which needs to be avoided by users with software.

## 14.5 IrDA

The USART module supports the control of IrDA infrared transceivers for physical layer communication. To use IrDA, you must clear the LINEN, STOP, and HDSEL bits. NRZ (Non-return-to-zero) coding is used between the USART module and the SIR physical layer (Infrared transceiver) to support up to 115200bps rates.

IrDA is a half-duplex protocol. If USART is sending data to SIR, the IrDA decoder will ignore the new infrared signal. If USART is receiving data from SIR, SIR will not accept the signal from USART. The level logic sent by USART to SIR and SIR to USART is different. In the SIR receiving logic, the high level is 1 and the low level is 0, but in the SIR sending logic, the high level is 0 and the low level is 1.

## 14.6 DMA

The USART module supports the DMA function, which can be utilized to achieve fast continuous sending and receiving. When DMA is enabled, the DMA writes data from a set memory space to the transmit buffer when TXE is set. When receiving with DMA, each time RXNE is set, DMA transfers the data in the receive buffer to a specific memory space.

## 14.7 Interrupts

The USART module supports a variety of interrupt sources, including transmit data register empty (TXE), CTS, transmit complete (TC), receive data ready (RXNE), data overflow (ORE), line idle (IDLE), parity error (PE),

disconnect flag (LBD), noise (NE), overflow for multi-buffered communication (ORT), and frame error (FE), among others.

Table 14-1 Relationship between interrupts and corresponding enable bits

| Interrupt source                                 | Enable bit |
|--|------------|
| Transmit data register empty (TXE)               | TXEIE      |
| Allowed to send (CTS)                            | CTSIE      |
| Transmission complete (TC)                       | TCIE       |
| Received data ready to be read (RXNE)            | RXNEIE     |
| Overrun error detected (ORE)                     |            |
| Idle line detected (IDLE)                        | IDLEIE     |
| Parity error (PE)                                | PEIE       |
| Break flag (LBD)                                 | LBDIE      |
| Noise flag (NE)                                  | EIE        |
| Overflow of multi-buffered communication (ORE)   |            |
| Frame error for multibuffered communication (FE) |            |

## 14.8 Register Description

Table 14-2 USART1-related registers list

| Name             | Offset address | Description              | Reset value |
|------------------|----------------|--------------------------|-------------|
| R32_USART1_STATR | 0x40013800     | UASRT Status Register    | 0x000000C0  |
| R32_USART1_DATAR | 0x40013804     | UASRT Data Register      | 0x00000XXX  |
| R32_USART1_BRR   | 0x40013808     | UASRT Baud Rate Register | 0x00000000  |
| R32_USART1_CTLR1 | 0x4001380C     | UASRT Control Register 1 | 0x00000000  |
| R32_USART1_CTLR2 | 0x40013810     | UASRT Control Register 2 | 0x00000000  |
| R32_USART1_CTLR3 | 0x40013814     | UASRT Control Register 3 | 0x00000000  |
| R32_USART1_GPR   | 0x40013818     | USART Prescaler Register | 0x00000000  |

Table 14-3 USART2-related registers list

| Name             | Offset address | Description              | Reset value |
|------------------|----------------|--------------------------|-------------|
| R32_USART2_STATR | 0x40004400     | UASRT Status Register    | 0x000000C0  |
| R32_USART2_DATAR | 0x40004404     | UASRT Data Register      | 0x00000XXX  |
| R32_USART2_BRR   | 0x40004408     | UASRT Baud Rate Register | 0x00000000  |
| R32_USART2_CTLR1 | 0x4000440C     | UASRT Control Register 1 | 0x00000000  |
| R32_USART2_CTLR2 | 0x40004410     | UASRT Control Register 2 | 0x00000000  |
| R32_USART2_CTLR3 | 0x40004414     | UASRT Control Register 3 | 0x00000000  |
| R32_USART2_GPR   | 0x40004418     | USART Prescaler Register | 0x00000000  |

### 14.8.1 USART Status Register (USARTx\_STATR) (x=1/2)

Offset address: 0x00

| Bit     | Name     | Access | Description  | Reset value |
|---------|----------|--------|--|-------------|
| [31:10] | Reserved | RO     | Reserved   | 0           |
| 9       | CTS      | RW0    | CTS status change flag. If the CTSE bit is set, when the nCTS output state changes, the bit will be set high by the hardware. Zero is cleared by the software. If the CTSIE bit has been set, an interrupt occurs.<br>1: There is a change in the nCTS state line;<br>0: There is no change on the nCTS state line.  | 0           |
| 8       | LBD      | RW0    | LINBreak detection flag. When a LINBreak is detected, the bit is set by the hardware. Zero is cleared by the software. If the LBDIE is already set, an interrupt will occur.<br>1: LIN Break detected;<br>0: No pending LIN Break was detected.  | 0           |
| 7       | TXE      | RO     | Transmit data register null flag. When the data in the TDR register is transferred by hardware to the shift register, the bit is set by the hardware. If the TXEIE has been set, an interrupt will occur, write to the data register, and this bit will be reset.<br>1: The data has been transferred to the shift register;<br>0: The data has not been transferred to the shift register.              | 1           |
| 6       | TC       | RW0    | Transmit completion flag. When a frame containing data is sent and the TXE is set, the hardware will have this bit, and if the TCIE is set, there will be a corresponding interrupt, which will be cleared by the software after reading this bit and writing the data register. You can also write 0 directly to clear this bit.<br>1: Transmit completed;<br>0: The transmission is not completed yet. | 1           |
| 5       | RXNE     | RW0    | Read the data register non-empty flag, when the data in the shift register is transferred to the data  | 0           |

|   |      |    |   |   |
|---|------|----|---|---|
|   |      |    | <p>register, the bit will be set by the hardware. If the RXNEIE has already been set, a corresponding interrupt will also occur. The bit can be cleared by reading the data register. You can also write 0 directly to clear the bit.</p> <p>1: The data is received and can be read;<br/>0: The data hasn't been received yet.</p>   |   |
| 4 | IDLE | RO | <p>Bus idle flag. When the bus is idle, the bit will be set by the hardware. If the IDLEIE is already set, a corresponding interrupt occurs. Reading the status register and then reading the data register clears this bit.</p> <p>1: The bus is idle;<br/>0: No idle bus was detected.</p> <p><i>Note: This bit will not be set again until RXNE is set.</i></p>  | 0 |
| 3 | ORE  | RO | <p>Overload error flag. This bit will be set when there is data in the receiving shift register that needs to be transferred to the data register, but there is still data in the receiving domain of the data register that has not been read. If RXNEIE is set, there will also be a corresponding interrupt.</p> <p>1: Overload error occurred;<br/>0: There is no overload error.</p> <p><i>Note: When an overload error occurs, the value of the data register will not be lost, but the value of the shift register will be overwritten. If the EIE bit is set, the ORE flag position bit will be interrupted in multi-buffer communication mode.</i></p> | 0 |
| 2 | NE   | RO | <p>Noise error flag. When a noise error flag is detected, it is set by the hardware. After reading the status register, the operation of reading the data register resets this bit.</p> <p>1: Noise detected;<br/>0: No noise was detected.</p> <p><i>Note: There is no interruption in this bit. If the EIE bit is set, the FE flag position bit will be interrupted in multi-buffer communication mode.</i></p>   | 0 |
| 1 | FE   | RO | <p>Frame error flag. When synchronization errors, excessive noise or breakers are detected, the bit will be set by the hardware. The operation of reading this bit and then reading the data register resets this bit.</p> <p>1: Frame error detected;</p>  | 0 |

|   |    |    |  |   |
|---|----|----|--|---|
|   |    |    | 0: No frame error was detected.<br><i>Note: This bit will not cause interruption. If the EIE bit is set, the FE flag position bit will be interrupted in multi-buffer communication mode.</i>  |   |
| 0 | PE | RO | Check error flag. In the receive mode, if a parity error occurs, the hardware sets this bit. The operation of reading this bit and then reading the data register resets this bit. The software must wait for the RXNE flag bit to be set before clearing this bit. If the PEIE has been set before, then setting this bit will result in a corresponding interrupt.<br>1: A parity error occurred;<br>0: There are no check errors. | 0 |

### 14.8.2 USART Data Register (USARTx\_Datar) (x=1/2)

Offset address: 0x04

| Bit    | Name     | Access | Description   | Reset value |
|--------|----------|--------|---|-------------|
| [31:9] | Reserved | RO     | Reserved  | 0           |
| [8:0]  | DR[8:0]  | RW     | Data register. This register is actually composed of two registers: the receive data register (RDR) and the transmit data register (TDR). The read and write operations of DR start with the read receive register (RDR) and the write send register (TDR). | X           |

### 14.8.3 USART Baud Rate Register (USARTx\_BRR) (x=1/2)

Offset address: 0x08

| Bit     | Name               | Access | Description   | Reset value |
|---------|--------------------|--------|---|-------------|
| [31:16] | Reserved           | RO     | Reserved  | 0           |
| [15:4]  | DIV_Mantissa[11:0] | RW     | These 12 bits define the integer portion of the divider division factor.  | 0           |
| [3:0]   | DIV_Fraction[3:0]  | RW     | These four digits define the decimal part of the divider division factor. | 0           |

**14.8.4 USART Control Register 1 (USARTx\_CTLR1) (x=1/2)**

Offset address: 0x0C

|          |    |    |      |     |    |      |       |      |        |        |    |    |     |     |    |
|----------|----|----|------|-----|----|------|-------|------|--------|--------|----|----|-----|-----|----|
| 31       | 30 | 29 | 28   | 27  | 26 | 25   | 24    | 23   | 22     | 21     | 20 | 19 | 18  | 17  | 16 |
| Reserved |    |    |      |     |    |      |       |      |        |        |    |    |     |     |    |
| 15       | 14 | 13 | 12   | 11  | 10 | 9    | 8     | 7    | 6      | 5      | 4  | 3  | 2   | 1   | 0  |
| Reserved | UE | M  | WAKE | PCE | PS | PEIE | TXEIE | TCIE | RXNEIE | IDLEIE | TE | RE | RWU | SBK |    |

| Bit     | Name     | Access | Description   | Reset value |
|---------|----------|--------|---|-------------|
| [31:14] | Reserved | RO     | Reserved  | 0           |
| 13      | UE       | RW     | USART enable bit. When this bit is set, both the frequency divider and output of the USART will stop working after the current byte transfer is complete.   | 0           |
| 12      | M        | RW     | Word length.<br>1: 9 data bits;      0: 8 data bits.  | 0           |
| 11      | WAKE     | RW     | Wake-up position. This bit determines how to wake up USART.<br>1: Address mark      0: The bus is idle.   | 0           |
| 10      | PCE      | RW     | Check bit enable. For the receiver, it is the parity of the data; for the sender, the parity bit is inserted. Once this bit is set, the parity bit enable will not take effect until the current byte transfer is complete. | 0           |
| 9       | PS       | RW     | Parity selection. 0 indicates even parity and 1 indicates odd parity. When this bit is set, the parity bit enable will not take effect until the current byte transfer is complete.   | 0           |
| 8       | PEIE     | RW     | Parity check interrupt enable bit. This bit means that a parity error interrupt is allowed.   | 0           |
| 7       | TXEIE    | RW     | Transmit buffer null interrupt enable. This bit indicates that a null interrupt in the transmit buffer is allowed.  | 0           |
| 6       | TCIE     | RW     | Transmit completed interrupt enable. This position bit means that a transmission completion interrupt is allowed.   | 0           |
| 5       | RXNEIE   | RW     | The receive buffer is not null interrupt enable. This bit indicates that a non-null interrupt in the receive buffer is allowed.   | 0           |
| 4       | IDLEIE   | RW     | Bus idle interrupt enable. This position bit means that a bus idle interrupt is allowed.  | 0           |
| 3       | TE       | RW     | Transmit enable. Setting this bit will enable the   | 0           |

|   |     |    |  |   |
|---|-----|----|--|---|
|   |     |    | transmitter.   |   |
| 2 | RE  | RW | Receive enable. Setting this bit enables the receiver, which begins to detect the start bit on the RX pin.   | 0 |
| 1 | RWU | RW | Receive wake-up call. This bit determines whether to put the USART in silent mode.<br>1: The receiver is in silent mode;<br>0: The receiver is in normal operation mode.<br><i>Note 1: Before setting the RWU bit, the USART needs to receive a byte of data, otherwise it cannot be woken up idle by the bus in silent mode.</i><br><i>Note 2: When configured to wake up with an address tag, the RWU bit cannot be modified by software when RXNE is set.</i> | 0 |
| 0 | SBK | RW | Transmit frame break character control bits. Set this bit to send a frame break character. When the stop bit of the frame is disconnected, it is reset by hardware.<br>1: Transmit;<br>0: Do not transmit.   | 0 |

**14.8.5 USART Control Register 2 (USARTx\_CTLR2) (x=1/2)**

Offset address: 0x10

| Bit     | Name      | Access | Description   | Reset value |
|---------|-----------|--------|---|-------------|
| [31:15] | Reserved  | RO     | Reserved  | 0           |
| 14      | LINEN     | RW     | LIN mode enable bit, setting enables LIN mode. In LIN mode, the LIN synchronization break symbol can be sent using the SBK bit and the LIN synchronization break can be detected. | 0           |
| [13:12] | STOP[1:0] | RW     | Stop setting the domain. These two will set the stop bit.<br>00: 1 stop bit;<br>01: 0.5 stop bit;<br>10: 2 stop bits;<br>11: 1.5 stop bits.                                       | 0           |
| [11:7]  | Reserved  | RW     | Reserved  | 0           |
| 6       | LBDIE     | RW     | LIN Break detects interrupt enable, which enables interrupts caused by LBD.   | 0           |

|       |          |    |  |   |
|-------|----------|----|--|---|
| 5     | LBDL     | RW | LIN Break detects the length, which is used to select whether to detect an 11-bit or 10-bit breaker. 1: 11-bit breaker detection; 0: 10-bit breaker detection.                 | 0 |
| 4     | Reserved | RW | Reserved   | 0 |
| [3:0] | ADD[3:0] | RW | Address domain, which is used to set the USART node address of this device. Used in silent mode in multiprocessor communication, using address tags to wake up a USART device. | 0 |

### 14.8.6 USART Control Register 3 (USARTx\_CTLR3) (x=1/2)

Offset address: 0x14

| Bit     | Name     | Access | Description  | Reset value |
|---------|----------|--------|--|-------------|
| [31:11] | Reserved | RO     | Reserved   | 0           |
| 10      | CTSIE    | RW     | CTSIE interrupt enable bit, which will cause an interrupt when CTS is set.   | 0           |
| 9       | CTSE     | RW     | CTS enable bit, which enables CTS flow control.  | 0           |
| 8       | RTSE     | RW     | RTS enable bit, which enables RTS flow control.  | 0           |
| 7       | DMAT     | RW     | DMA transmits enable bit. This location 1 uses DMA when transmitting.  | 0           |
| 6       | DMAR     | RW     | The DMA receives enable bit. This location 1 uses DMA when receiving.  | 0           |
| [5:4]   | Reserved | RO     | Reserved   | 0           |
| 3       | HDSEL    | RW     | Half-duplex mode selection bit, set this bit to select half-duplex mode.   | 0           |
| 2       | IRLP     | RW     | Infrared low-power selection bit, set this bit when selecting infrared, enable low-power mode.                                 | 0           |
| 1       | IREN     | RW     | Infrared enable bit, set this bit to enable infrared mode.   | 0           |
| 0       | EIE      | RW     | The error enables the interrupt bit. After setting this bit, if DMAR is set, if FE, ORE or NE is set, an interrupt will occur. | 0           |

### 14.8.7 USART Prescaler Register (USARTx\_GPR) (x=1/2)

Offset address: 0x18

| Bit    | Name     | Access | Description  | Reset value |
|--------|----------|--------|--|-------------|
| [31:8] | Reserved | RO     | Reserved   | 0           |
| [7:0]  | PSC[7:0] | RW     | Prescaler range.<br>In infrared low power mode, the source clock is divided by this value (Valid for all 8 bits), and a value of 0 indicates retention.<br>In infrared normal mode, this bit can only be set to 1. | 0           |

## Chapter 15 Inter-integrated Circuit (I2C) interface

*The module description in this chapter applies only to CH32V002, CH32V004, CH32V005, CH32V006, CH32V007, and CH32M007 products.*

The internal integrated circuit bus (I2C) is widely used in the communication between microcontrollers, sensors and other off-chip modules. It supports multi-master and multi-slave mode, and can communicate at both 100KHz (Standard) and 400KHz (Fast) speeds using only two wires (SDA and SCL).

### 15.1 Main Features

- Support master and slave modes
- Support 7-bit or 10-bit addresses
- Slave devices support dual 7-bit addresses
- Support two speed modes: 100KHz and 400KHz
- Multiple status modes, multiple error flags
- Support extended clock function
- 2 interrupt vectors
- DMA support
- Support PEC

### 15.2 Overview

I2C is a half-duplex bus, which can only run in one of the following four modes: master device transmitting mode, master device receiving mode, slave device transmitting mode and slave device receiving mode. The I2C module works in slave mode by default. After generating the starting condition, it will automatically switch to the master mode. When the arbitration is lost or a stop signal is generated, it will switch to the slave mode. The I2C module supports multi-host functions. When working in master mode, the I2C module will actively send out data and addresses. Data and addresses are transmitted in 8-bit units, with the high bit in front and the low bit in the back. After the start event is a byte (7-bit address mode) or two-byte (10-bit address mode) address. Every time the host sends 8-bit data or address, the slave needs to reply a reply ACK, that is, pull down the SDA bus, as shown in figure 15-1.

Figure 15-1 I2C Timing Diagram

In order to use it normally, the correct clock must be input to I2C. In standard mode, the lowest input clock is 2MHz,

and in fast mode, the lowest input clock is 4MHz.

Figure 15-2 is the functional block diagram of the I2C module.

Figure 15-2 Functional block diagram of the I2C module

### 15.3 Master Mode

In master mode, the I2C module dominates the data transmission and outputs the clock signal. The data transmission begins with the start event and ends with the end event. The steps to communicate using main mode are:

Set the correct clock in the control register 2 (R16\_I2C1\_CTLR2) and the clock control register (R16\_I2C1\_CKCFGR);

Set the appropriate rising edge in the rising edge register (R16\_I2C1\_RTR);

Set the PE bit in the control register (R16\_I2C1\_CTLR1) to start the peripheral;

Set the START bit in the control register (R16\_I2C1\_CTLR1) to generate a start event.

After setting the START bit, the I2C module will automatically switch to the main mode, the MSL bit will be set, and the starting event will be generated. After the initial event is generated, the SB bit will be set, and if the ITEVTEN bit (in R16\_I2C1\_CTLR2) is set, it will be interrupted. At this point, the status register 1 (R16\_I2C1\_STAR1) should be read. After writing from the address to the data register, the SB bit will be cleared automatically.

If the 10-bit address mode is used, then write the data register send header sequence (the header order is listed as 11110xx0b, where the xx bit is the highest two bits of the 10-bit address).

After sending the header sequence, the ADD10 bit of the status register will be set, and if the ITEVTEN bit has been set, an interrupt will occur. After reading the R16\_I2C1\_STAR1 register, write the second address byte to the data register, and clear the ADD10 bit.

Then write the data register to send the second address byte. After sending the second address byte, the ADDR bit

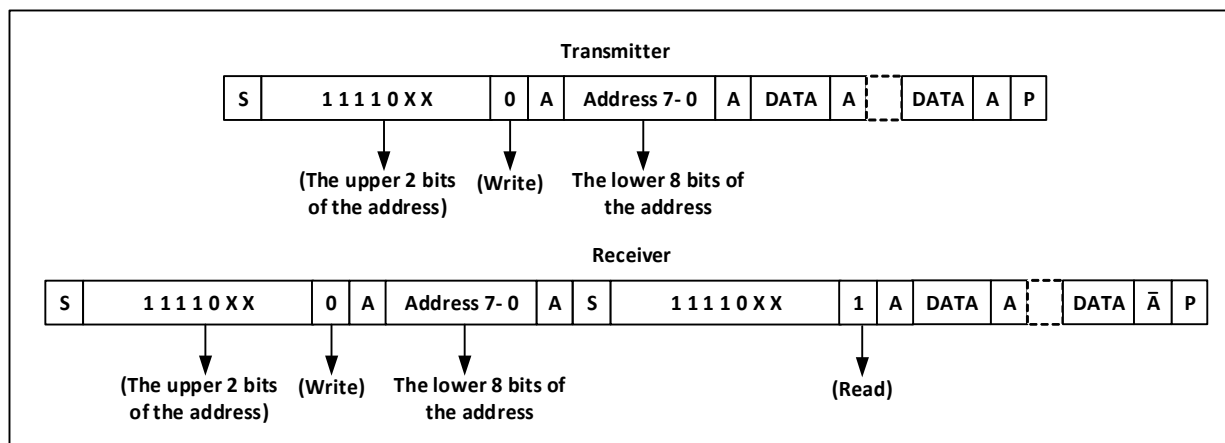

of the status register will be set. If the ITEVTEN bit has been set, it will cause an interrupt. In this case, you should read the R16\_I2C1\_STAR1 register and read the R16\_I2C1\_STAR2 register again to clear the ADDR bit.

If the 7-bit address mode is used, the write data register sends address bytes. After the address bytes are sent, the ADDR bit of the status register will be set, and if the ITEVTEN bit has been set, an interrupt will occur. At this time, you should read the R16\_I2C1\_STAR1 register and read the R16\_I2C1\_STAR2 register again to clear the ADDR bit.

In 7-bit address mode, the first byte sent is the address byte, the first 7 bits represent the address of the target slave device, the 8th bit determines the direction of the subsequent message, 0 indicates that the master device writes data to the slave device, and 1 represents that the master device reads information from the slave device.

In the 10-bit address mode, as shown in Figure 15-3, during the send address phase, the first byte is 11110xx0, xx is the highest 2 bits of the 10-bit address, and the second byte is the lower 8 bits of the 10-bit address. If you subsequently enter the master device transmit mode, you will continue to send data; if you subsequently prepare to enter the master device receive mode, you will need to re-send a start condition to follow the sending of a byte as 11110xx1, and then enter the master device receive mode.

Figure 15-3 Schematic diagram of master transmitting and receiving data at 10-bit address

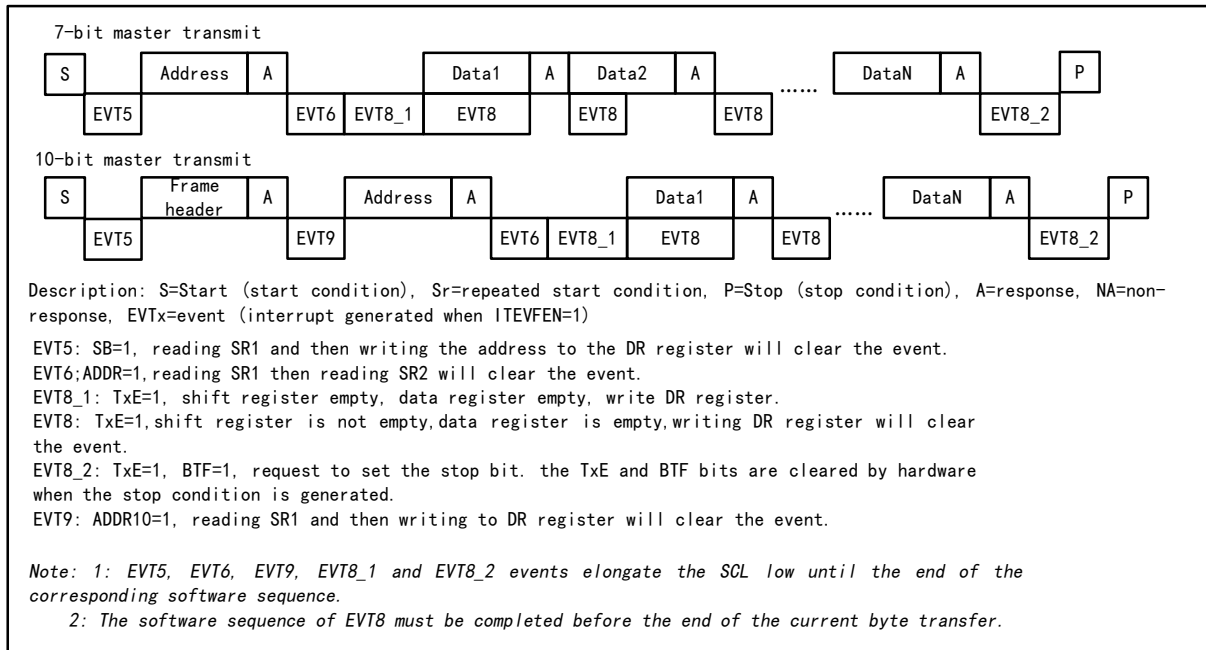

Master transmit mode:

The shift register inside the main device transmits data from the data register to the SDA line. When the master device receives the ACK, the TxE of the status register 1 (R16\_I2C1\_STAR1) is set, and an interrupt occurs if the ITEVTEN and ITBUFEN are set. Writing data to the data register clears the TxE bit.

If the TxE bit is set and no new data is written to the data register before the last data is sent, then the BTF bit will be set, the SCL will remain low until it is cleared, and after reading the R16\_I2C1\_STAR1, writing data to the data register will clear the BTF bit.

Figure 15-4 Master transmitter transmission sequence diagram

Master receive mode:

The I2C module receives data from the SDA line and writes it into the data register through the shift register. After each byte, if the ACK bit is set, the I2C module will issue a low level of reply, while the RxNe bit will be set, and if ITEVTEN and ITBUFEN are set, there will be an interruption. If the RxNE is set and the original data is not read before the new data is received, the BTF bit will be set, the SCL will remain low before clearing the BTF, and reading the R16\_I2C1\_STAR1 and then reading the data register will clear the BTF bit.

Figure 15-5 Receiver transmission sequence diagram

When the master device ends sending data, it will actively send an end event, that is, set the STOP bit, and I2C will switch to slave mode. In the receive mode, the master device needs to NAK at the answer position of the last data bit. After receiving the NACK, the slave device releases control over the SCL and SDA lines; the master device can send a stop / restart condition. Note that after the stop condition is generated, the I2C module will automatically

switch to slave mode.

## 15.4 Slave Mode

In the slave mode, the I2C module can recognize its own address and broadcast call address. The software can control the identification of broadcast call addresses on or off. Once the start event is detected, the I2C module compares the SDA data through the shift register with its own address (the number of bits depends on ENDUAL and ADDMODE) or the broadcast address (when ENGC is set). If it does not match, it will ignore it until a new start event is generated; if it matches the header sequence, it will generate an ACK signal and wait for the address of the second byte. If the address of the second byte also matches or the entire segment of the address matches in the case of a 7-bit address, then:

First generate an ACK response;

The ADDR bit is set, and if the ITEVTEN bit is set, there will be a corresponding interrupt

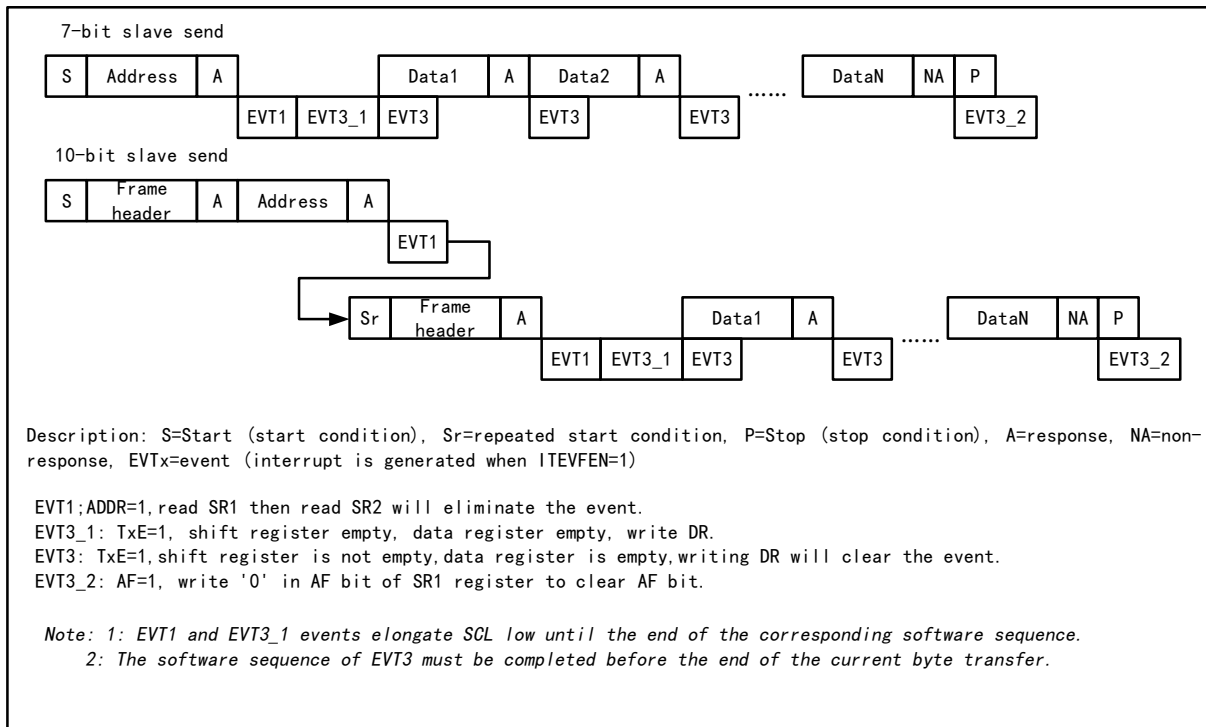

If you are using dual-address mode (the ENDUAL bit is set), you also need to read the DUALF bit to determine which address the host is calling.

The slave mode defaults to receive mode, after the last bit of the received header sequence is 1, or the last bit of the 7-bit address is 1 (Depending on whether the header sequence is received for the first time or a normal 7-bit address), when a duplicate starting condition is received, the I2C module will enter sender mode, and the TRA bit will indicate whether it is currently in receiver or sender mode.

Slave transmit mode:

After clearing the ADDR bit, the I2C module transmits bytes from the data register to the SDA line through the shift register. The slave device maintains the SCL at a low level until the ADDR bit is cleared and the data to be transmitted has been written to the data register. (see EVT1 and EVT3 in the following figure). Upon receipt of a reply ACK, the TXE bit is set, and an interrupt occurs if ITEVTEN and ITBUFEN are set. If TxE is set but no new data is written to the data register before the end of the next data transmission, the BTF bit will be set. The SCL will remain low until the BTF is cleared, and after reading the status register 1 (R16\_I2C1\_STAR1), writing data to the data register will clear the BTF bit.

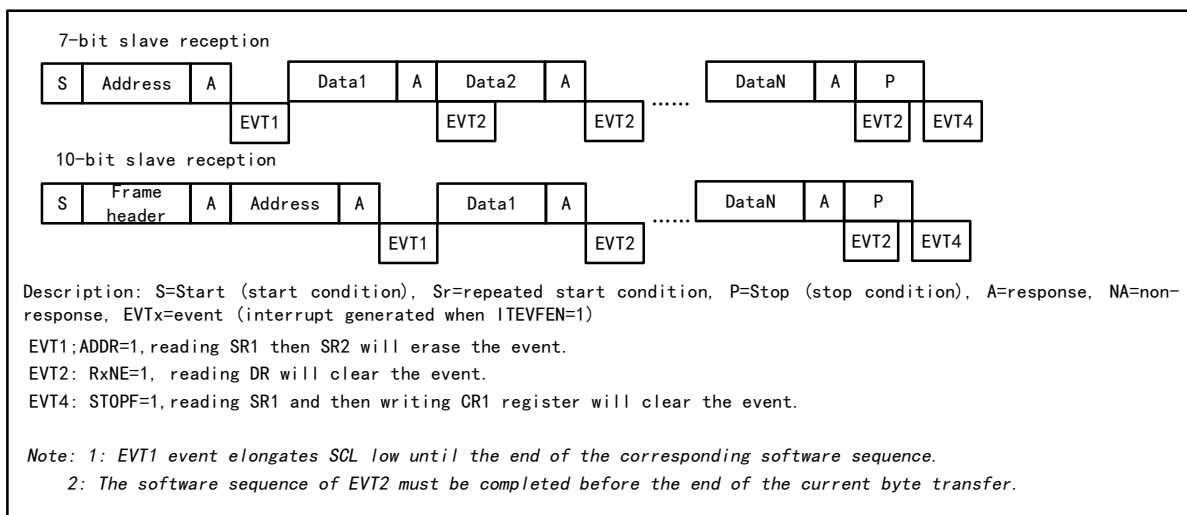

Figure 15-6 Slave transmitter transmission sequence diagram

Slave receive mode:

After the ADDR is cleared, the I2C module stores the data on the SDA into the data register through the shift register. After each byte is received, the I2C module will set an ACK bit and a RxNE bit. If ITEVTEN and ITBUFEN are set, an interrupt is also generated. If the RxNE is set and the old data is not read out before the new data is received, then the BTF will be set. The SCL stays low until the BTF bit is cleared. Reading the status register 1 (R16\_I2C1\_STAR1) and reading the data in the data register clears the BTF bit.

Figure 15-7 Receiver transmission sequence diagram

After the master device transmits the last data byte, it will produce a stop condition. When the I2C module detects the stop event, it will set the STOPF bit, and if the ITEVFEN bit is set, it will also produce an interrupt. The user needs to read the status register (R16\_I2C1\_STAR1) and then write the control register (Such as the reset control word SWRST) to clear. (See EVT4 in the figure above).

## 15.5 Error Conditions

### 15.5.1 Bus Error (BERR)

When the I2C module detects an external start or stop event during address or data transmission, a bus error occurs. When a bus error is generated, the BERR bit is set, and an interrupt occurs if ITERREN is set. In slave mode, the data is discarded and the hardware releases the bus. If it is a start signal, the hardware will consider it as a restart signal and start waiting for the address or stop signal; if it is a stop signal, it will operate according to the normal stop condition in advance. In master mode, the hardware does not release the bus and does not affect the current transmission, and it is up to the user code to decide whether to abort the transmission.

### 15.5.2 Acknowledge Failure (AF)

When the I2C module detects no response after a byte, a reply error occurs. When a reply error is generated: AF will be set, and an interrupt will be generated if ITERREN is set; if an AF error is encountered, if the I2C module works in slave mode, the hardware must release the bus, and if it is in master mode, the software must generate a stop event.

### 15.5.3 Arbitration Lost (ARLO)

When the I2C module detects the arbitration loss, an arbitration loss error occurs. When an arbitration loss error occurs: the ARLO bit is set and an interrupt is generated if ITERREN is set; the I2C module switches to slave mode and no longer responds to slave-initiated transfers against it unless a host initiates a new start event; the hardware releases the bus.

### 15.5.4 Overrun/underrun Error (OVR)

#### ● Overrun error

In slave mode, if clock extension is prohibited, the I2C module is receiving data. If one byte of data has been received, but the last received data has not been read out, an overload error will occur. When an overload error occurs, the last received byte is discarded and the sender should resend the last sent byte.

#### ● Underrun error

In slave mode, if clock extension is prohibited, the I2C module is sending data, and if new data is not written to the data register before the next byte clock arrives, an underload error will occur. When an underload error occurs, the data in the previous data register will be sent twice. If an underload error occurs, the receiver should discard the repeatedly received data. In order not to generate underload errors, the I2C module should write data to the data register before the first rising edge of the next byte.

## 15.6 Clock Extension

If clock extension is prohibited, there is a possibility of overload / underload errors. But if the clock is extended when enabled:

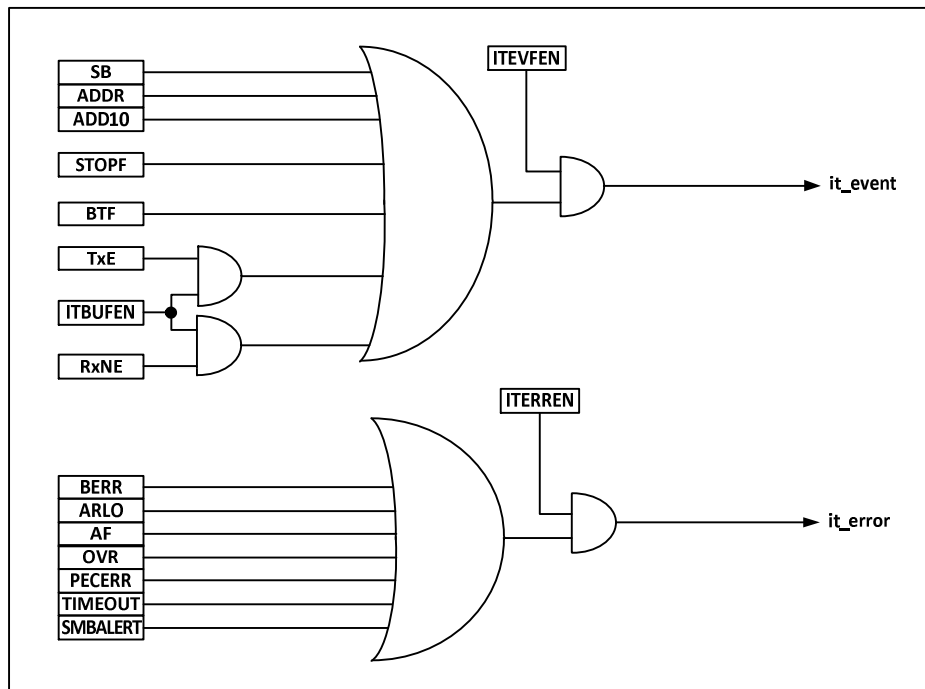

- In transmit mode, if TxE is set and BTF is set, the SCL will remain low, waiting for the user to read the status register and write the data to be sent to the data register;
- In receive mode, if RxNE is set and BTF is set, the SCL will remain low after receiving the data until the user reads the status register and reads the data register.

Thus it can be seen that the extension of the enable clock can avoid overload / underload errors.

## 15.7 Interrupts

Each I2C module has two kinds of interrupt vectors, which are event interrupt and error interrupt. The two interrupts support the interrupt source in figure 15-8.

Figure 15-8 I2C Interrupt Request

## 15.8 DMA

You can use DMA to send and receive bulk data. The ITBUFEN bit of the control register cannot be set when using DMA.

- Use DMA to transmit

The DMA mode can be activated by setting the DMAEN position bit of the CTLR2 register. As long as the TxE bit is set, the data will be loaded by the DMA from the set memory into the I2C data register. The following settings are required to assign channels to I2C.

- 1) The I2C1\_DATAR register address is set to the DMA\_PADDRx register, and the memory address is set in the DMA\_MADDRx register, so that after each TxE event, data is sent from the memory to the I2C1\_DATAR register.
- 2) Set the required number of transfer bytes in the DMA\_CNTRx register. This value is decremented after each TxE event.
- 3) Configure the channel priority using the PL[0:1] bits in the DMA\_CFGRx register.
- 4) Set the DIR bit in the DMA\_CFGRx register, and according to the application requirements, you can configure to issue an interrupt request when the whole transmission is half or all complete.
- 5) Activate the channel by setting the EN bit on the DMA\_CFGRx register.

When the number of data transmission bytes set in the DMA controller has been completed, the DMA controller sends an EOT/EOT\_1 signal at the end of the transmission to the I2C interface. If the interrupt allows, an DMA interrupt will be generated.

- Use DMA to receive

After setting the DMAEN of the CTLR2 register, the DMA receiving mode can be carried out. When receiving using DMA, DMA transfers the data in the data register to a preset memory area. The following steps are required to assign channels to I2C.

- 1) The I2C1\_DATAR register address is set to the DMA\_PADDRx register, and the memory address is set in the DMA\_MADDRx register, so that after each RxNE event, the data is written from the I2C1\_DATAR register to the memory.
- 2) Set the required number of transfer bytes in the DMA\_CNTRx register. This value is decremented after each RxNE event.
- 3) Configure the channel priority with PL [0:1] in the DMA\_CFGRx register.
- 4) Clear the DIR bit in the DMA\_CFGRx register, and according to the application requirements, it can be set to issue an interrupt request when half or all of the data transmission is completed.
- 5) Set the EN bit in the DMA\_CFGRx register to activate the channel.

When the number of data transmission bytes set in the DMA controller has been completed, the DMA controller sends an EOT/EOT\_1 signal at the end of the transmission to the I2C interface. If the interrupt allows, an DMA interrupt will be generated.

## 15.9 Packet Error Checking

Packet error check (PEC) is a step to add a CRC8 check to provide transmission reliability, using the following polynomials to calculate each bit of serial data:

$$C=X^8+X^2+X+1$$

PEC computing is activated by the ENPEC bit of the control register and calculates all bytes of information, including address and read-write bits. When sending, enabling PEC will add a CRC8 calculation result after the last byte of data; while in the receive mode, the last byte is considered to be the CRC8 check result, and if it does not match the internal calculation result, it will reply a NAK. If it is the main receiver, it will reply a NAK regardless of whether the check result is correct or not.

## 15.10 Register Description

Table 15-1 I2C-related registers list

| Name            | Offset address | Description            | Reset value |
|-----------------|----------------|------------------------|-------------|
| R16_I2C1_CTLR1  | 0x40005400     | I2C Control Register 1 | 0x0000      |
| R16_I2C1_CTLR2  | 0x40005404     | I2C Control Register 2 | 0x0000      |
| R16_I2C1_OADDR1 | 0x40005408     | I2C Address Register 1 | 0x0000      |
| R16_I2C1_OADDR2 | 0x4000540C     | I2C Address Register 2 | 0x0000      |
| R16_I2C1_DATAR  | 0x40005410     | I2C Data Register      | 0x0000      |
| R16_I2C1_STAR1  | 0x40005414     | I2C Status Register 1  | 0x0000      |
| R16_I2C1_STAR2  | 0x40005418     | I2C Status Register 2  | 0x0000      |
| R16_I2C1_CKCFGR | 0x4000541C     | I2C Clock Register     | 0x0000      |

| F/S | DUTY | Reserved | CCR[11:0] |    |    |   |   |   |   |   |   |   |   |   |   |

| Bit     | Name      | Access | Description   | Reset value |
|---------|-----------|--------|---|-------------|
| 15      | F/S       | RW     | Master mode selection bit.<br>1: Fast mode;<br>0: Standard mode.                                | 0           |
| 14      | DUTY      | RW     | Duty cycle in fast mode:<br>1: $T_{Low}/T_{High} = 16/9$ ;<br>0: $T_{Low}/T_{High} = 2$ .       | 0           |
| [13:12] | Reserved  | RO     | Reserved  | 0           |
| [11:0]  | CCR[11:0] | RW     | Clock frequency division coefficient domain, determine the frequency waveform of the SCL clock. | 0           |

## Chapter 16 Serial Peripheral Interface (SPI)

The module description in this chapter applies only to CH32V002, CH32V004, CH32V005, CH32V006, CH32V007, and CH32M007 products.

SPI supports data exchange in three-wire synchronous serial mode, plus chip line selection supports hardware switching between master and slave modes, and supports communication with a single data line.

### 16.1 Main Features

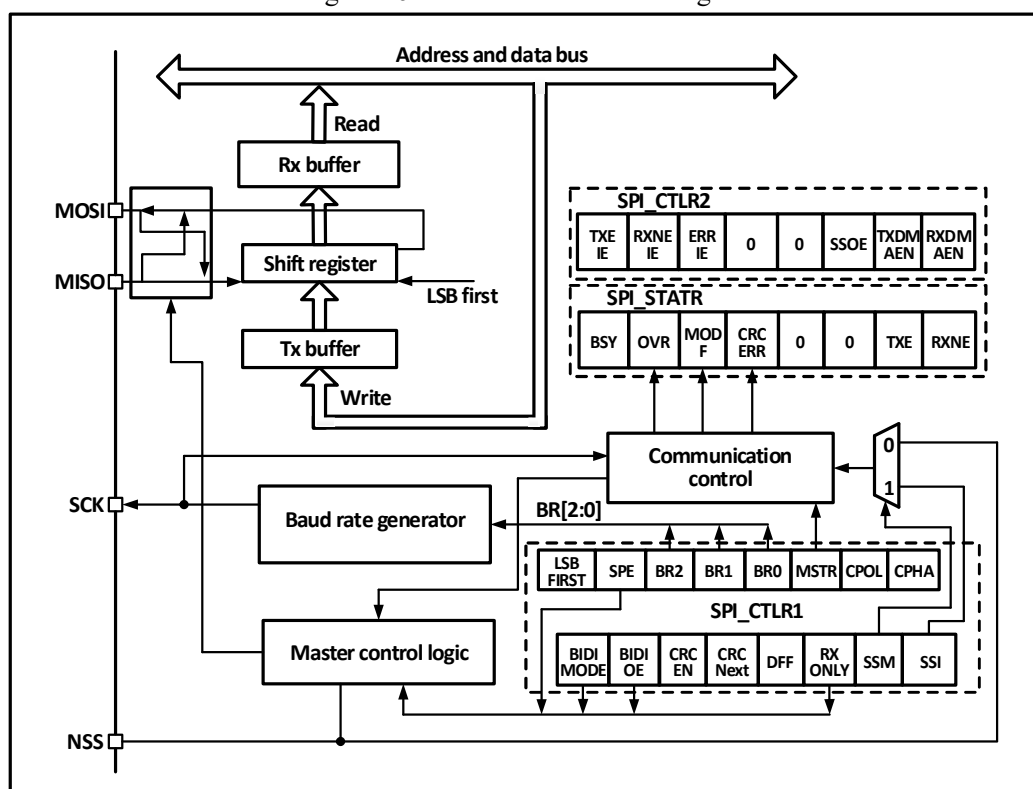

#### 16.1.1 SPI Features

- Support full-duplex synchronous serial mode
- Support single-wire half-duplex mode
- Support Master mode and Slave mode, multi-slave mode
- Support 8-bit or 16-bit data structures
- Maximum clock frequency supports up to half of  $F_{HCLK}$
- Data order supports MSB or LSB first
- Support hardware or software control of NSS pins
- Hardware CRC checksum support for sending and receiving
- Transceiver buffers support DMA transfers
- Support modification of clock phase and polarity

### 16.2 Function Description

#### 16.2.1 Overview

Figure 16-1 SPI structure block diagram

As can be seen from Figure 16-1, the main SPI-related pins are MISO, MOSI, SCK and NSS. The MISO pin is a data input pin when the SPI module is working in master mode; it is a data output pin when it is working in slave mode. The MOSI pin is a data output pin when the SPI module is working in master mode; it is a data input pin when it is working in slave mode. The SCK is a clock pin. The clock signal is always output from the host, and the slave receives the clock signal and synchronizes the data sending and receiving. The NSS pin is a chip select pin and has the following usage:

- 1) NSS is controlled by software: When SSM is set, the internal NSS signal is determined by SSI whether the output is high or low. This case is generally used in SPI main mode.
- 2) NSS is controlled by hardware: When NSS output is enabled, that is, when SSOE is set, when the SPI host sends output, it will actively pull down the NSS pin. If the NSS pin is not successfully pulled, it means that other master devices on the main line are communicating, and a hardware error will occur; if SSOE is not set, it can be used in multi-host mode. If it is pulled down, it will be forced to enter the slave mode, and the MSTR bit will be automatically cleared.

The operating mode of SPI can be configured through CPHA and CPOL. The CPHA setting indicates that the module samples the data at the second edge of the clock, and the data is latched, while the CPHA setting indicates that the SPI module samples at the first edge of the clock, and the data is latched. CPOL indicates whether the countless data clock is high or low.

The host and device need to be set to the same SPI mode, and the SPE bit needs to be cleared before configuring SPI mode. The DEF bit can determine whether the single data length of the SP is 8 or 16 bits. LSBFIRST can control whether a single data word is high or low.

Table 16-1 SPI schema differentiation

|      | Mode 0 | Mode 1 | Mode 2 | Mode 3 |
|------|--------|--------|--------|--------|
| CPOL | 0      | 1      | 1      | 1      |
| CPHA | 0      | 0      | 0      | 1      |

### 16.2.2 Master Mode

When the SPI module works in the main mode, the serial clock is generated by the SCK. Configure to main mode to perform the following steps:

Configure the BR [2:0] field of the control register to determine the clock;

Configure the CPOL and CPHA bits to determine the SPI mode;

Configure DEF to determine data word length;

Configure LSBFIRST to determine frame format;

Configure the NSS pin, such as setting the SSOE bit to let the hardware set the NSS. You can also set the SSM bit and make the SSI position high;

To set the MSTR bit and the SPE bit, you need to make sure that the NSS is already high.

When you need to transmit data, you only need to write the data to be transmitted to the data register. SPI will send the data from the send buffer to the shift register in parallel, and then send the data from the shift register as set by LSBFIRST. When the data has reached the shift register, the TXE flag will be set, and if TXEIE has been set, an interrupt will occur. If the TXE flag position bit needs to fill the data register, maintain the complete data flow.

When the receiver receives the data, when the last sampling clock edge of the data word arrives, the data is transferred from the shift register to the receive buffer in parallel, the RXNE bit is set, and an interrupt occurs if the RXNEIE bit is previously set. At this point, the data register should be read and the data should be removed as soon as possible.

Figure 16-2 SPI master mode read/write mode 0

Figure 16-3 SPI master mode read/write mode 1

Figure 16-4 SPI master mode read/write mode 2

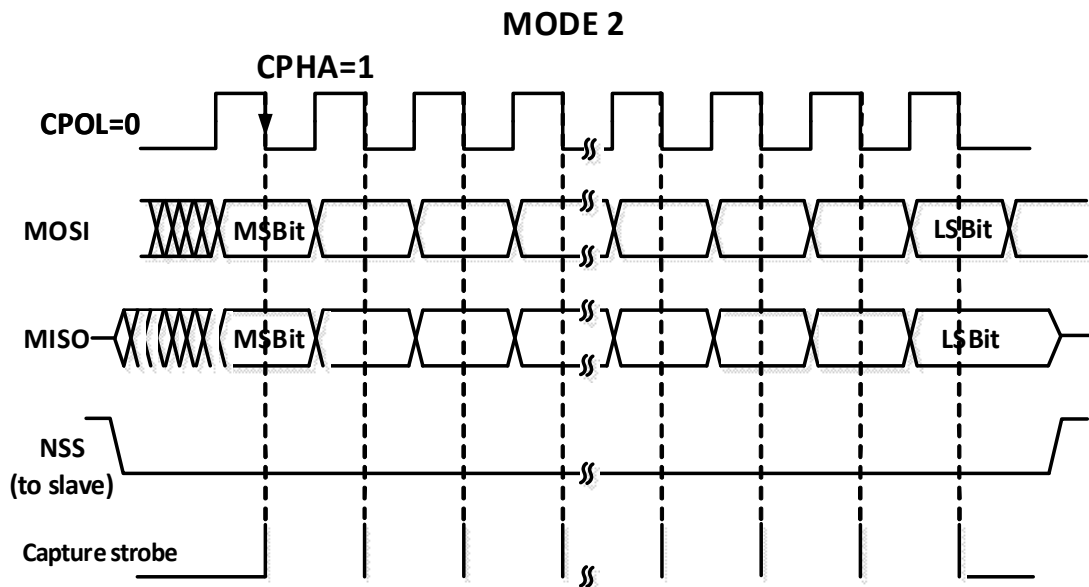

Figure 16-5 SPI master mode read/write mode 3

### 16.2.3 Slave Mode

When the SPI module works in slave mode, SCK is used to receive the clock sent by the host, and its own baud rate setting is invalid. The steps to configure to slave mode are as follows:

Configure the DEF bit to set the data bit length;

Configure CPHA to match the host operating mode;

The working mode of SPI is determined according to the configuration of transceiver and CPOL.

If you need to send in slave mode, you need to set CPOL to mode 2 or mode 3, and the host will change the configuration as needed.

If you only need to receive from the mode, you only need to match the host CPOL mode.

Configure LSBFIRST to match host data frame format;

In hardware management mode, the NSS pin needs to be kept low. If NSS is set to software management (SSM setting), please keep the SSI not set.

Clear MSTR bit, set SPE bit, turn on SPI mode.

At the time of transmission, when the first slave receiving sampling edge appears in the SCK, the slave starts sending. The process of sending is that the data of the send buffer is moved to the send shift register. When the data of the send buffer is moved to the shift register, the TXE flag will be set. If the TXEIE bit is set before, then an interrupt will occur.

When receiving, after the last clock sampling edge, the RXNE bit is set, the bytes received by the shift register are transferred to the receiving buffer, and the data in the receiving buffer can be obtained by reading the data register. If the RXNEIE is set before the RXNE is set, an interruption occurs.

Figure 16-6 SPI slave mode read/write mode 0

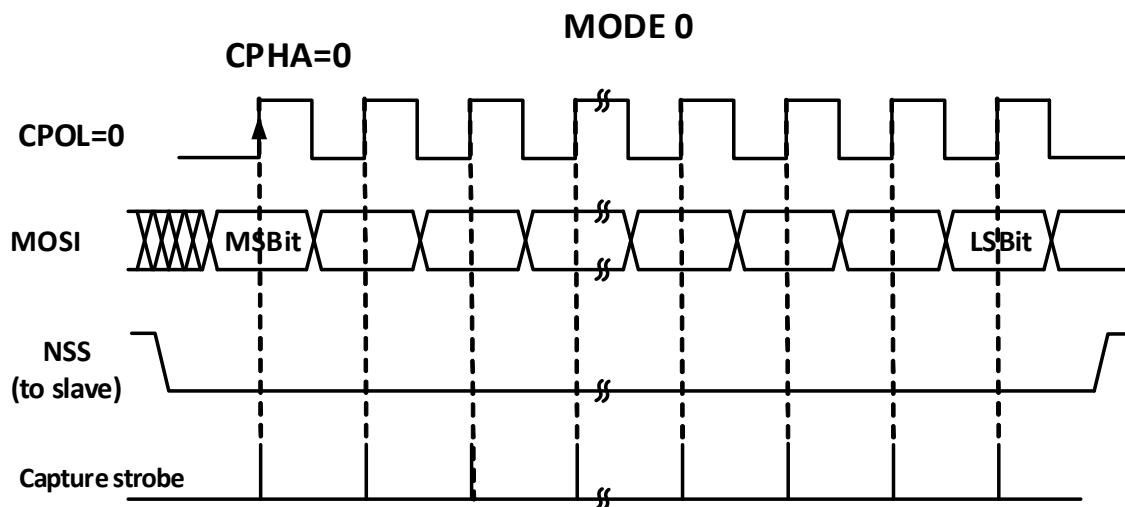

Figure 16-7 SPI slave mode read/write mode 1

Figure 16-8 SPI slave mode read/write mode 2

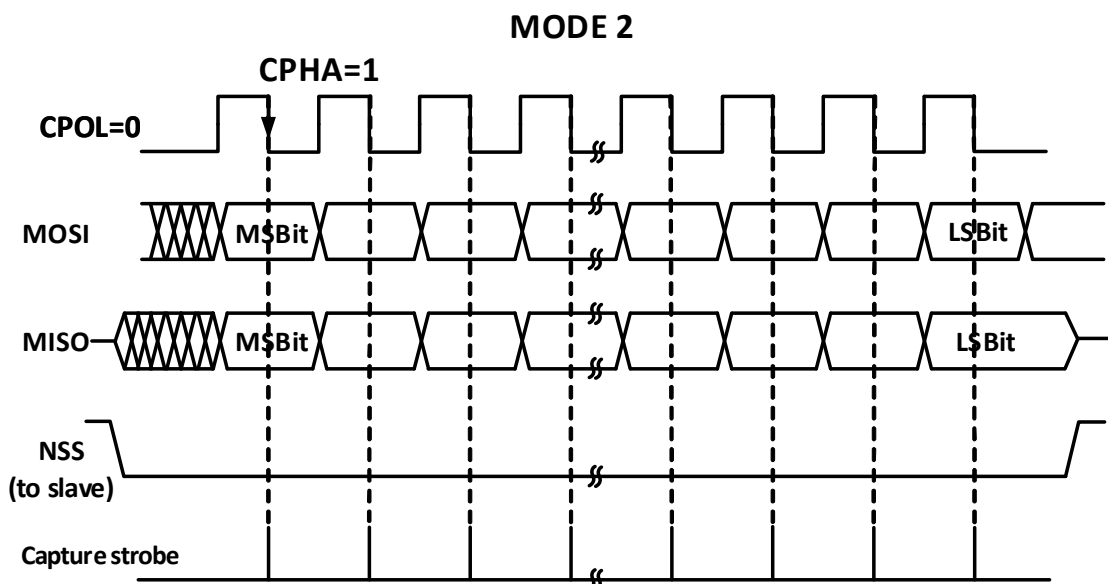

Figure 16-9 SPI slave mode read/write mode 3

### 16.2.4 Simplex Mode

The SPI interface can operate in half-duplex mode, where the master device uses the MOSI pin and the slave device uses the MISO pin for communication. When using half-duplex communication, you need to set BIDIMODE and use BIDIOE to control the transmission direction.

Setting the RXONLY bit in normal full-duplex mode sets the SPI module to receive-only simplex mode, releasing a data pin after RXONLY is set. The SPI can also be set to transmit only mode by ignoring the received data.

### 16.2.5 CRC

The SPI module uses CRC checksum to ensure the reliability of full-duplex communication, and separate CRC calculators are used for data sending and receiving. the polynomial for CRC calculation is determined by the

polynomial register, and different calculations are used for 8-bit data width and 16-bit data width, respectively. Setting the CRCEN bit will enable CRC checksum and at the same time will reset the CRC calculator. After the last data byte is sent, setting the CRCNEXT bit will send the TXCRCR calculator calculation after the current byte is sent, while the CRCERR bit will be set if the last received receive shift register value does not match the locally calculated RXCRCR calculation. Using the CRC checksum requires setting the polynomial calculator and setting the CRCEN bit when configuring the SPI operating mode, and setting the CRCNEXT bit on the last word or half-word to send the CRC and perform the receive CRC checksum. Note that the polynomial for the CRC calculation should be unified for both transmitting and receiving.

### 16.2.6 DMA

The SPI module supports the use of DMA to speed up data communication, either by using DMA to fill the transmit buffer or by using DMA to pick up data from the receive buffer in a timely manner. DMA will pick up or send data in a timely manner using RXNE and TXE as signals. DMA can also operate in simplex or CRC mode.

### 16.2.7 Errors

- Master mode fault (MODF)

When the SPI is operating in NSS pin hardware management mode, an external pull-down of the NSS pin occurs; or in NSS pin software management mode, the SSI bit is cleared; or the SPE bit is cleared, causing the SPI to be shut down; or the MSTR bit is cleared and the SPI enters slave mode. If the ERRIE bit is already set, an interrupt is also generated. Steps to clear the MODF bit: First perform a read or write operation to R16\_SPI1\_STATR, and then write R16\_SPI1\_CTLR1.

- Overrun condition

If the host transmits data and there is unread data in the receive buffer of the slave device, an overflow error occurs, the OVR bit is set, and an interrupt is also generated if ERRIE is set. Transmitting an overflow error should restart the current transmission. Reading the data register and then reading the status register will eliminate this bit.

- CRC error

When the received CRC word and the value of RXCRCR do not match, a CRC error will be generated and the CRCERR bit will be set.

### 16.2.8 Interrupts

The SPI module supports five interrupt sources, among which the TXE and RXNE events are set when the TXEIE and RXNEIE bits are set respectively. In addition to the above three errors will also generate interrupts, namely MODF, OVR and CRCERR, after enabling the ERRIE bit, these three errors will also generate error interrupts.

## 16.3 Register Description

Table 16-2 SPI-related registers list

| Name           | Offset address | Description            | Reset value |
|----------------|----------------|------------------------|-------------|
| R16_SPI1_CTLR1 | 0x40013000     | SPI Control Register 1 | 0x0000      |

### 16.3.4 SPI Data Register (SPI\_DATAR)

Offset address: 0x0C

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

| Bit    | Name     | Access | Description  | Reset value |
|--------|----------|--------|--|-------------|
| [15:0] | DR[15:0] | RW     | Data register. The data register is used to store the received data or pre-store the data to be sent, so the read and write of the data register is actually corresponding to the different operation area, in which the read pair uses the receiving buffer and the write corresponds to the transmitting buffer. The reception and transmission of data can be 8-bit or 16-bit, and how many bits of data need to be determined before transmission. When using 8 bits for data transmission, only the lower 8 bits of the data register are used, and the high 8 bits are forced to 0 when received. The use of 16-bit data structures causes all 16-bit data registers to be used. | 0           |

### 16.3.5 SPI Polynomial Register (SPI1\_CRCR)

Offset address: 0x10

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

| Bit | Name | Access | Description | Reset value |
|-----|------|--------|-------------|-------------|
|-----|------|--------|-------------|-------------|

|        |               |    |   |    |
|--------|---------------|----|---|----|
| [15:0] | CRCPOLY[15:0] | RW | CRC polynomials. This field defines the polynomials used in CRC calculations. | 7h |
|--------|---------------|----|---|----|

### 16.3.6 SPI Receive CRC Register (SPI1\_RCRCR)

Offset address: 0x14

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

|             |
|-------------|
| RXCRC[15:0] |
|-------------|

| Bit    | Name        | Access | Description   | Reset value |
|--------|-------------|--------|---|-------------|
| [15:0] | RXCRC[15:0] | RO     | Receive CRC value. The calculated result of the CRC check of the received bytes is stored. Setting CRCEN resets the register. The calculation method uses the polynomials used by CRCPOLY. In 8-bit mode, only the lower 8 bits participate in the calculation, while in 16-bit mode, all 16 bits participate in the calculation. You need to read this register when BSY is 0. | 0           |

### 16.3.7 SPI Transmit CRC Register (SPI1\_TCRCR)

Offset address: 0x18

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

|             |
|-------------|
| TXCRC[15:0] |
|-------------|

| Bit    | Name        | Access | Description   | Reset value |
|--------|-------------|--------|---|-------------|
| [15:0] | TXCRC[15:0] | RO     | Transmit CRC. Stores the calculated results of the CRC check of the bytes that have been sent. Setting CRCEN resets the register. The calculation method uses the polynomials used by CRCPOLY. In 8-bit mode, only the lower 8 bits participate in the calculation, while in 16-bit mode, all 16 bits participate in the calculation. You need to read this register when BSY is 0. | 0           |

### 16.3.8 SPI High-speed Control Register (SPI1\_HSCR)

| 0 | HSRXEN | RW | Read enable in SPI high-speed mode:<br>1: Enable high-speed reading mode;<br>0: Disable high-speed reading mode. | 0 |
|---|--------|----|--|---|

## Chapter 17 Operational Amplifier (OPA) and Comparator (CMP)

*This chapter OPA module description applies only to CH32V005, CH32V006, CH32V007 and CH32M007 products, where CH32V005 products do not have OPA polling functionality, and this chapter CMP module description applies only to CH32V007 and CH32M007 products.*

The module consists of an independently configurable operational amplifier (OPA or PGA) and an independently configurable voltage comparator (CMP1), as well as a voltage comparator (CMP2) used in conjunction with the operational amplifier, in which the operational amplifier (OPA or PGA) supports gain selection or can be used as a voltage comparator.

The input and output of the operational amplifier can be connected to the I/O port, and the input channel (Pin) and gain are optional, the output channel can be optionally configured to the general I/O port, and an additional internal output channel is directly connected to the ADC internal channel to support the external analog small signal amplification into the ADC to achieve small signal ADC conversion. High-speed mode is supported, and the pendulum rate can be increased by setting high-speed mode.

The input and output of each voltage comparator are connected to the I/O port, and the input pins are optional, and the output pins can be optionally configured to the universal I/O port or multiplexed as a TIM internal sampling channel (Without using the I/O pin).

### 17.1 Main Features

- OPA input channel (Pin) selectable
- The OPA output channel can be selected from the universal I/O port, and the internal output channel is directly connected to the ADC internal channel.
- OPA supports front-end input polling.
- OPA supports single-ended PGA, differential PGA and PGA gain selection.
- CMP1 input pin selectable
- The CMP output pin can choose either the universal I/O port or the TIM internal sampling channel.
- 1 interrupt vector

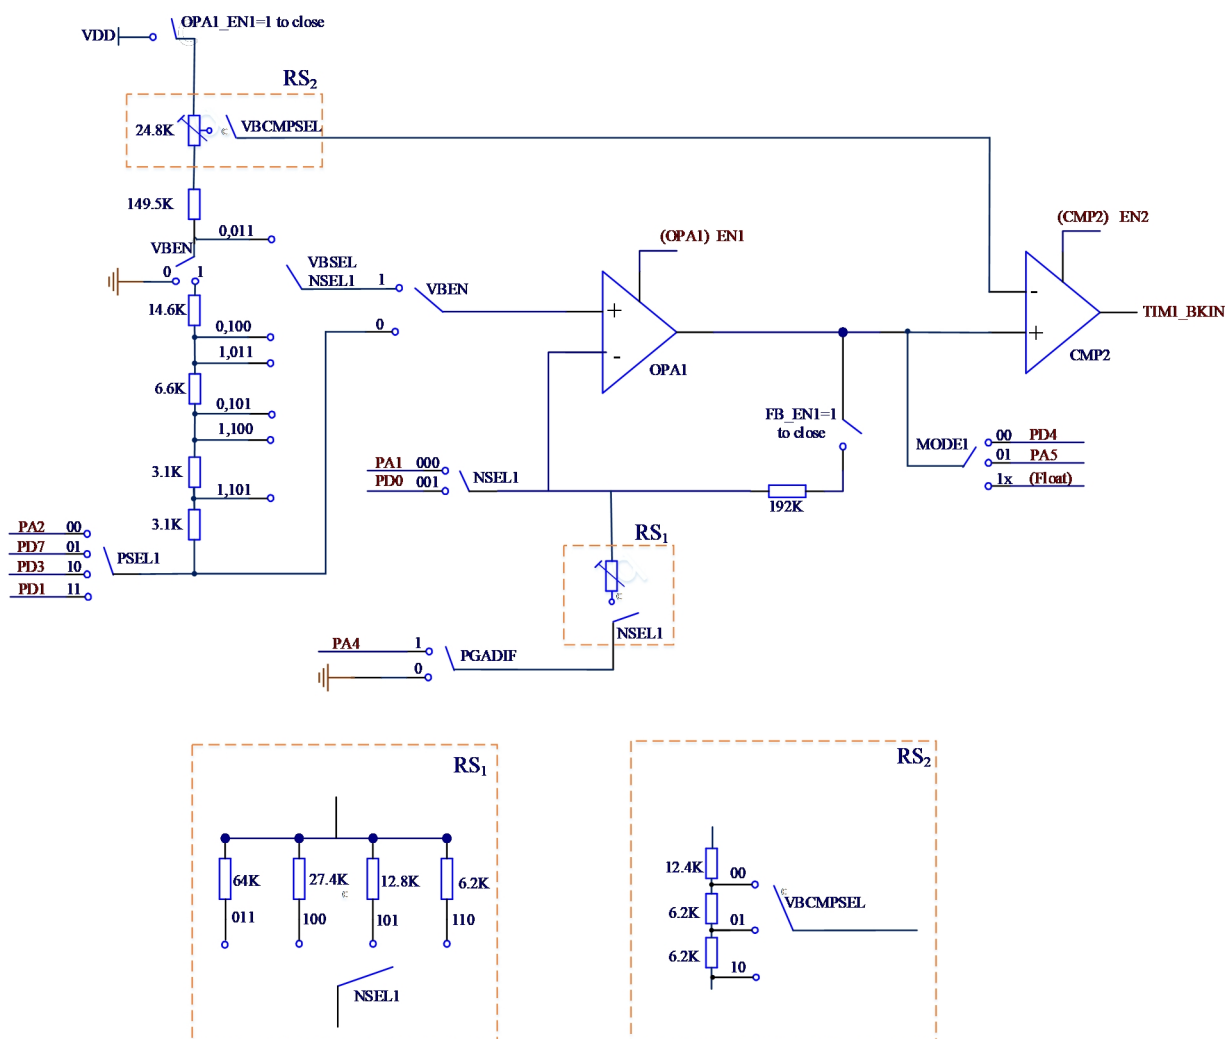

### 17.2 Function Description

#### 17.2.1 OPA

In the OPA\_CTLR1 register: configure the OPA\_EN1 bit to enable the OPA1; to configure the MODE1 bit to select the output channel of the OPA1; configure the PSEL1 bit to select the positive input pin of the OPA1; and configure the NSEL1 bit to select the negative input channel of the OPA1 or the gain when used as the PGA.

In the OPA\_CTLR1 register: configure the OPA\_HS1 bit to turn on the OPA1 high-speed mode and increase the swing rate to 40V/μs; configure the PGADIF bit to turn on the differential input PGA mode; configure the VBEN bit to turn on the bias function PGA mode, and cooperate with the CMP\_EN2 bit in the VBCMPSEL and OPA\_CTLR2 registers to compare the OPA output with the bias voltage.

Figure 17-1 OPA structure diagram

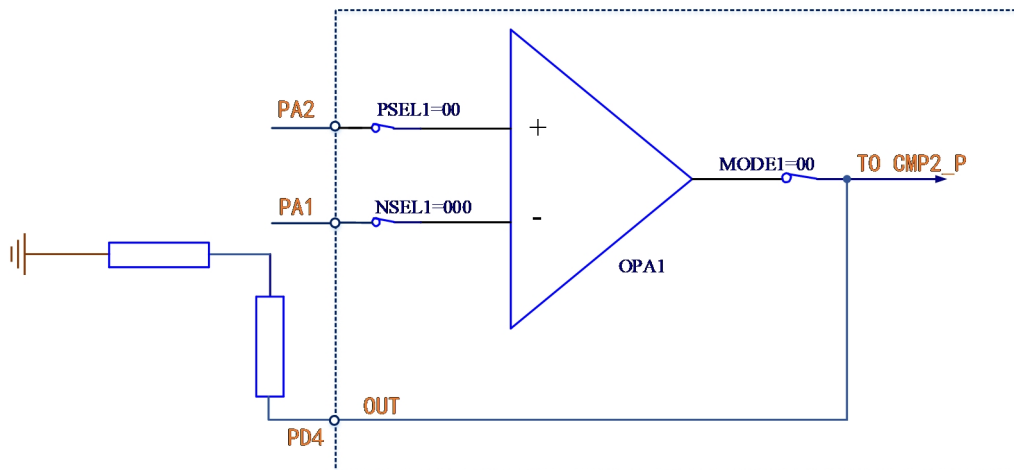

### 17.2.1.1 OPA Single-ended Input

In the OPA\_CTLR1 register: configure PSEL1 bit to select OPA1 positive and negative pin input; configure MODE1 bit to select OPA1 positive and negative pin output, and the corresponding pin is configured as analog input. After OPA\_EN1 position 1 enables OPA1, the external pin can be linked internally.

*Note: External access feedback resistor can be selected when using stand-alone OPA1.*

Figure 17-2 Schematic diagram of OPA single-ended input

Configuration actions:

1. Unlock OPA:

Write KEY1 = 0x45670123 to OPA\_KEY register (The first step must be KEY1);

Write KEY2 = 0xCDEF89AB to OPA\_KEY register (The second step must be KEY2).

2. Select OPA pin:

In the OPA\_CTLR1 register: Configure the PSEL1 bit to 00b (PA2), NSEL1 bit to 000b (PA1), and MODE1 bit to 00b (PD4).

3. In the OPA\_CTLR1 register: Configure the OPA\_EN1 bit to 1, enable OPA1.

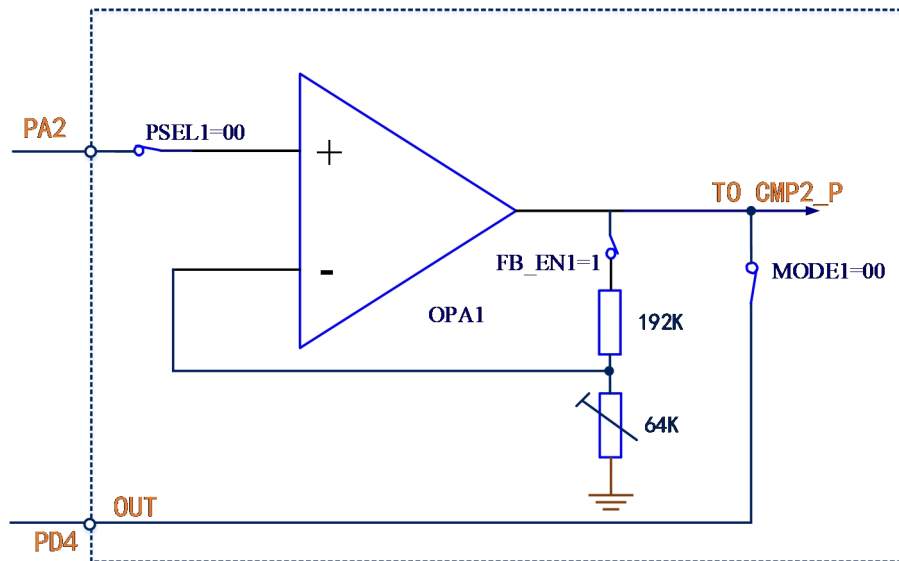

### 17.2.1.2 OPA Built-in Programmable PGA

In the OPA\_CTLR1 register: configure the PGADIF bit to 0, select the OPA single-ended mode, so that the negative input is internally grounded; configure the NSEL1 bit to be 011b, 100b, 101b, 1010b, the gain is: 4, 10, 100, 1010; configure the PSEL1 bit to select the positive input; configure the OPA\_EN1 bit to 1, enable OPA1.

Note:

- 1) In internally programmable PGA mode, the external pin only needs the input and output of the positive end of the OPA, and the negative input defaults to the internal ground.
- 2) After selecting the gain, in order to avoid output saturation, the input voltage should be lower than VDD divided by the gain multiple.

Figure 17-3 Schematic diagram of OPA internal programmable PGA

Configuration actions:

1. Unlock OPA:

Write KEY1 = 0x45670123 to OPA\_KEY register (The first step must be KEY1);

Write KEY2 = 0xCDEF89AB to OPA\_KEY register (The second step must be KEY2).

2. Select OPA pin:

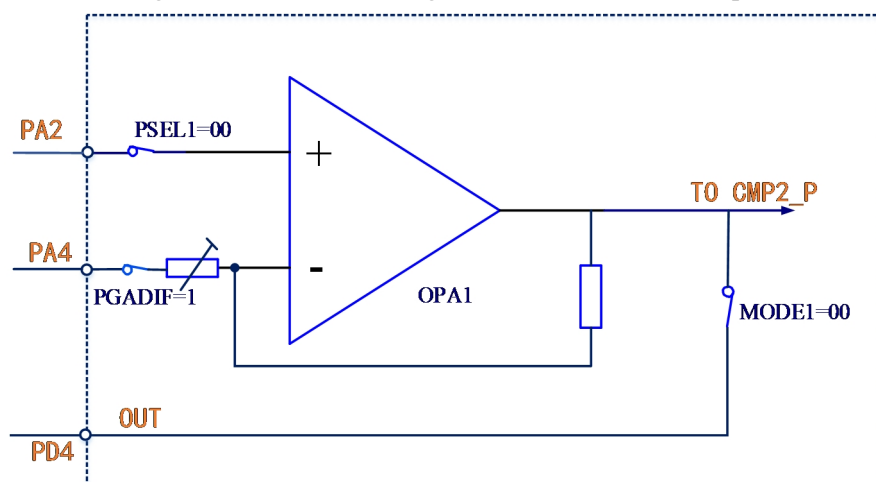

In the OPA\_CTLR1 register: Configure the PSEL1 bit to 00b (PA2), NSEL1 bit to 000b (PA1), and MODE1 bit to 00b (PD4).

3. In the OPA\_CTLR1 register: Configure the OPA\_EN1 bit to 1, enable OPA1.

### 17.2.1.3 OPA Differential Input

In the OPA\_CTLR1 register: configure the PGADIF bit to 1, select the OPA differential input PGA mode, then the negative input is configured with the NSEL1 bit 011b PGA, and the OPA\_EN1 bit is configured as 1 to enable internal feedback resistor; the PSEL1 bit is configured to select the positive input; and the OPA\_EN1 bit is configured as 1 to enable OPA1.

Figure 17-4 Schematic diagram of OPA differential input

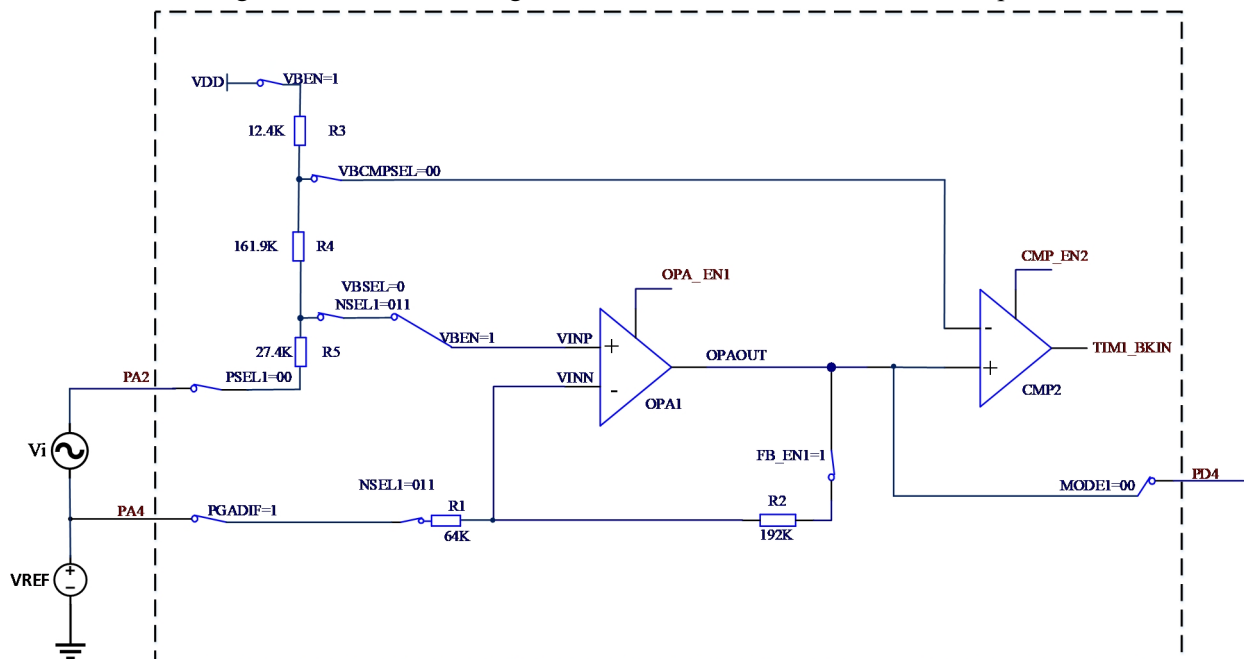

### 17.2.1.4 OPA Self-biased Differential PGA

When the OPA uses differential PGA, the bias voltage can be increased, and the output voltage can be connected to the positive input of the CMP2, and then compared with the negative reference voltage.

In the OPA\_CFGR2 register: configure the RST\_EN2 bit to 1 to enable the CMP2 reset function, when the CMP output is a high-level complex system, or configure the BKIN\_CFG bit of the OPA\_CTLR2 register to 10b as the brake source of the TIM1.

Figure 17-5 Schematic diagram of OPA self-offset differential PGA input

Configuration actions:

1. Unlock OPA:

Write KEY1 = 0x45670123 to OPA\_KEY register (The first step must be KEY1);

Write KEY2 = 0xCDEF89AB to OPA\_KEY register (The second step must be KEY2).

2. Select OPA pin:

In the OPA\_CTLR1 register: Configure OPA\_EN1 bit 1, enable OPA1; Configure PSEL1 bit 00b (PA2); NSEL is 011b, and FB\_EN1 position 1, enable internal feedback resistance; MODE1 is 00b (PD4).

3. Configure VBEN to 1b, enable output voltage bias; VBSEL is 0b, select PGA output reference voltage.

4. CMP unlock:

Write KEY1 = 0x45670123 to CMP\_KEY register (The first step must be KEY1);

Write KEY2 = 0xCDEF89AB to CMP\_KEY register (The second step must be KEY2).

5. In the OPA\_CTLR1 register: Configure the VBCMPSEL bit to 00b and give the reference voltage at the negative end of the CMP2.

6. In the OPA\_CFGR2 register: Configure BKIN\_CFG to 10b as the brake source of TIM1.

7. In the OPA\_CFGR2 register: Configure the CMP\_EN2 bit to 1, enable CMP2.

The calculation methods of OPA output bias voltage  $V_{B_{OPAOUT}}$ , OPA output AC gain  $Gain_{OPAOUT}$  and CMP negative terminal voltage  $V_{B_{CMP}}$  are given according to figure 17-5, as shown in Table 17-1, Table 17-2 and Table 17-3:

Table 17-1 OPA output bias voltage  $V_{B_{OPAOUT}}$

| VBSEL   | $V_{B_{OPAOUT}}$       |
|---------|------------------------|
| VBSEL=0 | $(V_{DD}+V_{REF})/2$   |
| VBSEL=1 | $V_{DD}/4+V_{REF}*3/4$ |

Table 17-2 OPA output AC gain Gain<sub>OPAOUT</sub>

| VBSEL   | Gain <sub>OPAOUT</sub> |
|---------|------------------------|
| VBSEL=0 | $((R1+R2)/R1)-0.5$     |
| VBSEL=1 | $((R1+R2)/R1)-0.25$    |

Table 17-3 CMP negative terminal voltage V<sub>B\_CMP</sub>

| VBCMPSEL    | V <sub>B_CMP</sub>    |
|-------------|-----------------------|
| VBCMPSEL=00 | $VDD*30/33+VINP*3/33$ |
| VBCMPSEL=01 | $VDD*29/33+VINP*4/33$ |
| VBCMPSEL=10 | $VDD*28/33+VINP*5/33$ |

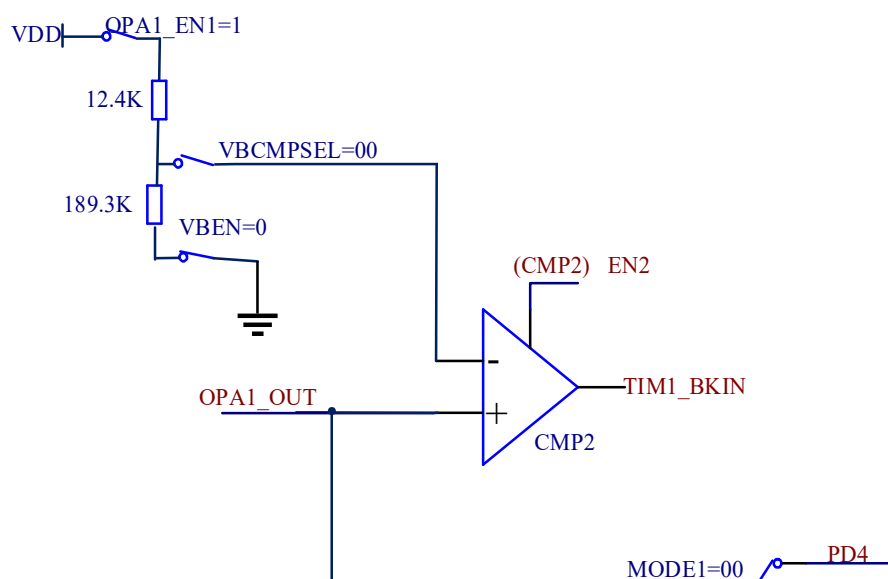

For applications where VREF is unknown, the AC gain can be obtained in similar ways as follows:

- 1) NSEL=011b, the ADC1 is obtained by sampling OPA\_OUT of the above-mentioned 1-7 ADC.
- 2) NSEL=100b, repeat the sampling OPA\_OUT of the above-mentioned 1-7, ADC samples OPA\_OUT to get ADC2.
- 3) Then  $V_i=(ADC2-ADC1)/4$ .

### 17.2.1.5 CMP2 Independent Bias Mode

When CMP2 is used alone, the negative bias voltage of CMP2 can be increased independently, and the output can be compared with the results of OPA1\_OUT. In the OPA\_CFGR2 register: configure the RST\_EN2 bit to 1, enable the CMP2 reset function, when the CMP output is the high-level reset system, or configure the BKIN\_CFG bit of the OPA\_CTLR2 register to 10b as the brake source of the TIM1.

Figure 17-6 Schematic diagram of CMP2 independent bias mode

Configuration actions:

1. Unlock OPA:

Write KEY1 = 0x45670123 to OPA\_KEY register (The first step must be KEY1);

Write KEY2 = 0xCDEF89AB to OPA\_KEY register (The second step must be KEY2).

2. Select OPA pin:

In OPA\_CTLR1 register: Configure OPA\_EN1 bit to 1, enable OPA1.

3. Configure VBEN to 0b, enable output voltage bias.

4. CMP unlock:

Write KEY1 = 0x45670123 to CMP\_KEY register (The first step must be KEY1);

Write KEY2 = 0xCDEF89AB to CMP\_KEY register (The second step must be KEY2).

5. In the OPA\_CTLR1 register: Configure the VBCMPSEL bit to 00b and give the reference voltage at the negative end of the CMP2.

6. In the OPA\_CFGR2 register: Configure BKIN\_CFG to 10b as the brake source of TIM1.

7. In the OPA\_CFGR2 register: Configure the CMP\_EN2 bit to 1, enable CMP2.

### 17.2.2 OPA Positive Input Polling

The P side of OPA can be selected from OPA\_P0/OPA\_P1/OPA\_P2, and the polling function of OPA can select OPA\_P0/OPA\_P1/OPA\_P2 in turn and select all P sides in turn; the OPA polling order can be set by configuring the POLL\_CHx bit in the OPA\_CFGR1 register, and the POLL\_EN bit can be configured to open the OPA1 positive end polling.

The number of channels polled can be configured through the POLL1\_NUM in the OPA\_CFGR1 register.

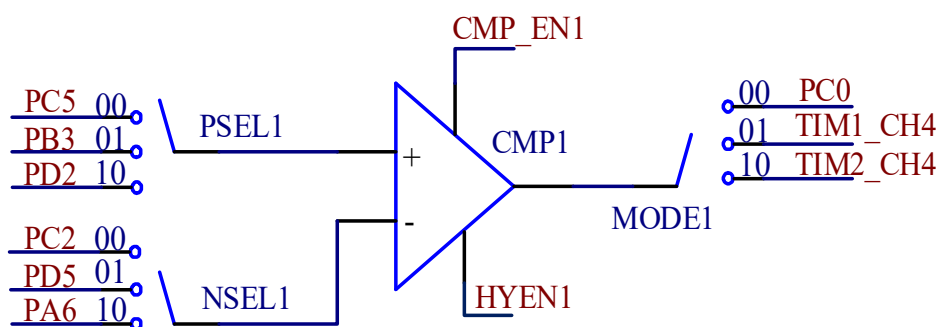

### 17.2.3 Comparator CMP

Setting the CMP\_ENx in the OPA\_CTLR2 register enables the corresponding CMPx.

In the OPA\_CTLR2 register: configure MODE1 bit to select the output channel of CMP1; configure PSEL1 to select the positive input pin of CMP1; configure NSEL1 to select the negative input pin of CMP1.

The CMP2 positive input pin comes from the OPA1 output and can select the channel through the MODE1 bit in the OPA\_CTLR1 register; the negative reference voltage is controlled by the VBCMPSEL bit in the OPA\_CTLR register and is valid only in VBEN=1. The output of CMP2 is used as the brake source of TIM1.

Figure 17-7 CMP structure diagram

## 17.3 Register Description

Table 17-4 OPA-related registers list

| Name          | Offset address | Description                  | Reset value |
|---------------|----------------|------------------------------|-------------|
| R32_OPA_CFGR1 | 0x40024000     | OPA Configuration Register 1 | 0x00000000  |

### 17.3.5 OPA Unlock Key Register 2 (OPA\_KEY)

Offset address: 0x10

| Bit    | Name          | Access | Description  | Reset value |
|--------|---------------|--------|--|-------------|
| [31:0] | OPA_KEY[31:0] | W0     | OPA key, the locking keys for input OPA include:<br>KEY1 = 0x45670123;<br>KEY2 = 0xCDEF89AB. | X           |

### 17.3.6 CMP Unlock Key Register (CMP\_KEY)

Offset address: 0x14

| Bit    | Name          | Access | Description  | Reset value |
|--------|---------------|--------|--|-------------|
| [31:0] | CMP_KEY[31:0] | W0     | CMP key, the locking keys for input CMP include:<br>KEY1 = 0x45670123;<br>KEY2 = 0xCDEF89AB. | X           |

### 17.3.7 POLL Lock Key Register (POLL\_KEY)

Offset address: 0x14

| Bit    | Name           | Access | Description  | Reset value |
|--------|----------------|--------|--|-------------|
| [31:0] | POLL_KEY[31:0] | W0     | Poll key, the locking keys for input POLL include:<br>KEY1 = 0x45670123;<br>KEY2 = 0xCDEF89AB.<br>After locking, it can be unlocked only if the system is reset. | X           |

## Chapter 18 Flash Memory and User Option Bytes (FLASH)

The module described in this chapter is suitable for the full range of CH32V00X microcontrollers.

### 18.1 Flash Memory Organization

The internal flash memory of the chip is organized as follows (Take CH32V006 as an example).

Table 18-1 Flash Memory Organization

| Block             | Name                 | Address Range             | Size (Byte) |
|-------------------|----------------------|---------------------------|-------------|
| Main memory       | Page 0               | 0x0800 0000 – 0x0800 00FF | 256         |
|                   | Page 1               | 0x0800 0100 – 0x0800 01FF | 256         |
|                   | Page 2               | 0x0800 0200 – 0x0800 02FF | 256         |
|                   | Page 3               | 0x0800 0300 – 0x0800 03FF | 256         |
|                   | ...                  | ...                       | ...         |
|                   | Page 247             | 0x0800 F700– 0x0800 F7FF  | 256         |
| Information block | Startup program code | 0x1FFF 0000 – 0x1FFF 0CFF | 3K+256      |
|                   | User option bytes    | 0x1FFF F800 – 0x1FFF F83F | 256         |

Note: The above main memory area is used for the user's application storage and is divided into write protection units in 2K bytes (8 pages).

### 18.2 Flash Memory Programming and Security

#### 18.2.1 Programming/Erasing Methods

- Fast programming: This method uses page operation (recommended). After a specific sequence of unlocking, it performs a single 256-byte programming and 256-byte erasing, 1K-byte erasing (standard 1K whole chip erasing is also applicable to fast programming).

#### 16.2.2 Security - Prevent Illegal Access (Read, Write, Erase)

- Page write protection
- Read protection

When the chip is in the read-protected state.

- 1) Main memory pages 0-7 (2K bytes) are automatically write-protected state, not controlled by FLASH\_WPR register; unread-protected state, all main memory pages are controlled by FLASH\_WPR register.
- 2) System boot code area, SWD (SDI) mode, RAM area cannot erase or program the main memory, except the whole chip erase. The user option byte area can be erased or programmed. If you try to unprotect the read (programming user words), the chip will automatically erase the entire user area.

Note: The internal RC oscillator (HSI) must be turned on when programming / erasing flash memory.

### 18.3 Register Description

Table 18-2 FLASH-related registers list

| Name            | Offset address | Description      | Reset value |
|-----------------|----------------|------------------|-------------|
| R32_FLASH_ACTLR | 0x40022000     | Control Register | 0x00000000  |

|                         |            |                           |            |
|-------------------------|------------|---------------------------|------------|
| R32_FLASH_KEYR          | 0x40022004 | FPEC Key Register         | 0xFFFFFFFF |
| R32_FLASH_OBKEYR        | 0x40022008 | OBKEY Register            | 0xFFFFFFFF |
| R32_FLASH_STATR         | 0x4002200C | Status Register           | 0x0000B000 |
| R32_FLASH_CTLR          | 0x40022010 | Configuration Register    | 0x00008080 |
| R32_FLASH_ADDR          | 0x40022014 | Address Register          | 0xFFFFFFFF |
| R32_FLASH_OBR           | 0x4002201C | Option Byte Register      | 0xFFFFFFFF |
| R32_FLASH_WPR           | 0x40022020 | Write Protection Register | 0xFFFFFFFF |
| R32_FLASH_MODEKEYR      | 0x40022024 | Extended Key Register     | 0xFFFFFFFF |
| R32_FLASH_BOOT_MODEKEYR | 0x40022028 | Unlock BOOT Key Register  | 0xFFFFFFFF |

### 18.3.1 Control Register (FLASH\_ACTLR)

Offset address: 0x00

| Bit    | Name         | Access | Description  | Reset value |
|--------|--------------|--------|--|-------------|
| [31:2] | Reserved     | RO     | Reserved   | 0           |
| [1:0]  | LATENCY[1:0] | RW     | FLASH wait status number.<br>00: 0 wait (Recommended 0<=SYSCLK<=15MHz);<br>01: 1 wait (Recommended 15<SYSCLK<=24MHz);<br>10: 2 wait (Recommended 24<SYSCLK<=48MHz);<br>11: Reserved. | 0           |

### 18.3.2 FPEC Key Register (FLASH\_KEYR)

Offset address: 0x04

| Bit    | Name       | Access | Description   | Reset value |
|--------|------------|--------|---|-------------|
| [31:0] | KEYR[31:0] | WO     | FPEC key, the unlock keys for entering FPEC include:<br>RDPRT key = 0x000000A5;<br>KEY1 = 0x45670123;<br>KEY2 = 0xCDEF89AB. | X           |

### 18.3.3 OBKEY Register (FLASH\_OBKEYR)

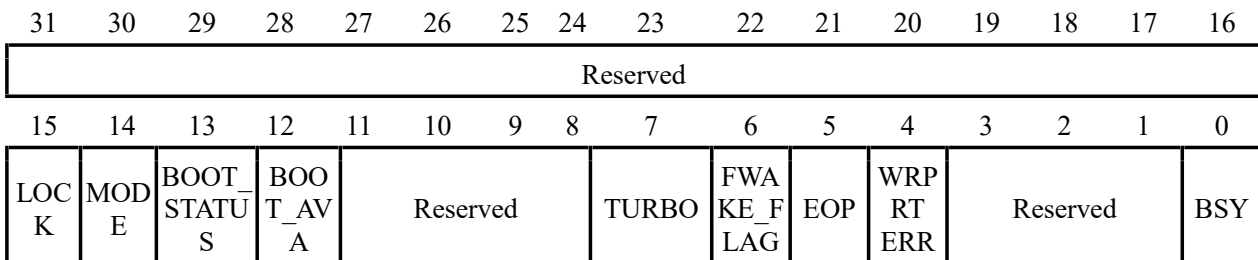

Offset address: 0x08

| Bit    | Name         | Access | Description  | Reset value |
|--------|--------------|--------|--|-------------|
| [31:0] | OBKEYR[31:0] | WO     | Option byte key, which is used to enter a select word key to release OPTWRE.<br>KEY1 = 0x45670123;<br>KEY2 = 0xCDEF89AB.<br>(Note: FLASH needs to be unlocked first) | X           |

### 18.3.4 Status Register (FLASH\_STATR)

Offset address: 0x0C

| Bit     | Name        | Access | Description   | Reset value |
|---------|-------------|--------|---|-------------|
| [31:16] | Reserved    | RO     | Reserved  | 0           |
| 15      | BOOT_LOCK   | RW     | BOOT lock.<br>1: Locked, unable to write to FLASH_STATA [14] field;<br>0: Unlock, you can write to the FLASH_STATR [14] field.<br><i>Note: Write 1 setting, write 0 is invalid.</i>                             | 1           |
| 14      | BOOT_MODE   | RW     | Combined with BOOT_AVA, the switch between user area and BOOT area can be controlled.<br>1: After software reset, you can switch to the BOOT area.<br>0: After software reset, you can switch to the user area. | 0           |
| 13      | BOOT_STATUS | RO     | The source of the currently executed program.<br>1: Indicates a program loaded from the BOOT area.  | 1           |
| 12      | BOOT_AVA    | RO     | Initializes the configuration word status.<br>1: Indicates booting from the BOOT area.  | 1           |
| [11:8]  | Reserved    | RO     | Reserved  | 0           |
| 7       | TURBO       | RO     | TURBO mode enable.<br>1: Indicates that you are in TURBO mode;<br>0: No effect.   | 0           |
| 6       | FWAKE_FLAG  | RW0    | FLASH wakeup flag, write 0 clear.   | 0           |

|       |          |     |  |   |
|-------|----------|-----|--|---|
|       |          |     | 1: FALSH is waken up;<br>0: No effect.   |   |
| 5     | EOP      | RW1 | Indicates the end of the operation, write 1 clear. The hardware is set each time it is successfully erased or programmed.    | 0 |
| 4     | WRPRERR  | RW1 | Indicates write protection error, write 1 clear. The hardware will set the address if it is programmed for write protection. | 0 |
| [3:1] | Reserved | RO  | Reserved   | 0 |
| 0     | BSY      | RO  | Indicates busy status.<br>1: Indicates that a flash operation is in progress.<br>0: End of operation.                        | 0 |

Note: When performing the programming operation, you need to make sure the STRT bit of FLASH\_CTLR register is 0.

### 18.3.5 Configuration Register (FLASH\_CTLR)

Offset address: 0x10

|          |          |         |       |          |       |        |          |           |          |      |      |            |             |      |          |
|----------|----------|---------|-------|----------|-------|--------|----------|-----------|----------|------|------|------------|-------------|------|----------|
| 31       | 30       | 29      | 28    | 27       | 26    | 25     | 24       | 23        | 22       | 21   | 20   | 19         | 18          | 17   | 16       |
| Reserved |          |         |       |          |       |        |          | BER<br>32 | Reserved |      |      | BUF<br>RST | BUF<br>LOAD | FTER | FTPG     |
| 15       | 14       | 13      | 12    | 11       | 10    | 9      | 8        | 7         | 6        | 5    | 4    | 3          | 2           | 1    | 0        |
| FLOCK    | Reserved | FWAKEIE | EOPIE | Reserved | ERRIE | OBWERE | Reserved | LOCK      | STRT     | OBER | OBPG | Reserved   | MER         | PER  | Reserved |

| Bit     | Name     | Access | Description   | Reset value |
|---------|----------|--------|---|-------------|
| [31:24] | Reserved | RO     | Reserved  | 0           |
| 23      | BER32    | RW     | Perform block erasure 32KB.   | 0           |
| [22:20] | Reserved | RO     | Reserved  | 0           |
| 19      | BUFRST   | RW     | Buffer BUF reset operation.   | 0           |
| 18      | BUFLOAD  | RW     | Cache the data into BUF.  | 0           |
| 17      | FTER     | RW     | Perform a fast page (256Byte) erase operation.  | 0           |
| 16      | FTPG     | RW     | Perform a quick page programming operation.   | 0           |
| 15      | FLOCK    | RW1    | Fast programming lock. You can only write '1'. When the bit is '1', quick programming / erase mode is not available. After the correct unlock sequence is detected, the hardware clears this bit as '0'.<br>The software is set to 1 and re-locked. | 1           |
| 14      | Reserved | RO     | Reserved  | 0           |
| 13      | FWAKEIE  | RW     | Wake up interrupt enable, when FLASH wakes up from low-power mode, it will generate a flag bit, if wake up interrupt enable is set, it will generate an interrupt signal, otherwise it will have no effect.   |             |

|    |          |     |   |   |
|----|----------|-----|---|---|
| 12 | EOPIE    | RW  | The operation completes the interrupt control (EOP setting in FLASH_STATR register).<br>1: Interrupts are allowed;<br>0: Interrupts is prohibited.  | 0 |
| 11 | Reserved | RO  | Reserved  | 0 |
| 10 | ERRIE    | RW  | Error status interrupt control (PGERR/WRPTERR set in FLASH_STATR register).<br>1: Interrupts are allowed;<br>0: Interrupts is prohibited.   | 0 |
| 9  | OBWRE    | RW0 | User option byte lock, software clears 0.<br>1: Indicates that the word selected by the user can be programmed. The correct sequence needs to be written in the FLASH_OBKEYR register and then set by the hardware.<br>0: The user option bytes are re-locked after the software is cleared.                | 0 |
| 8  | Reserved | RO  | Reserved  | 0 |
| 7  | LOCK     | RW1 | Lock. You can only write '1'. When the bit is '1', it means that FPEC and FLASH_CTLR are locked unwritable. After the correct unlock sequence is detected, the hardware clears this bit as '0'.<br>After an unsuccessful unlock operation, the bit will not change until the next time the system is reset. | 1 |
| 6  | STRT     | RW1 | Start. Setting 1 initiates an erase action, and the hardware clears 0 automatically (BSY becomes '0').  | 0 |
| 5  | OBER     | RW  | Perform user option byte erasure.   | 0 |
| 4  | OBPG     | RW  | Perform user option byte program.   | 0 |
| 3  | Reserved | RO  | Reserved  | 0 |
| 2  | MER      | RW  | Perform a full erase operation (erase the entire user area).  | 0 |
| 1  | PER      | RW  | Sector erasure (1K) is performed.   | 0 |
| 0  | Reserved | RO  | Reserved  | 0 |

### 18.3.6 Address Register (FLASH\_ADDR)

Offset address: 0x14

| Bit    | Name      | Access | Description   | Reset value |
|--------|-----------|--------|---|-------------|
| [31:0] | FAR[31:0] | WO     | Flash address, which is the programming address for programming and the starting address for erasure.<br>The register cannot be written when the BSY bit in the FLASH_SR register is '1'. | X           |

### 18.3.7 Option Byte Register (FLASH\_OBR)

Offset address: 0x14

|          |    |    |    |    |    |        |        |        |       |       |     |     |       |    |    |
|----------|----|----|----|----|----|--------|--------|--------|-------|-------|-----|-----|-------|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25     | 24     | 23     | 22    | 21    | 20  | 19  | 18    | 17 | 16 |
| Reserved |    |    |    |    |    |        | DATA1  |        |       |       |     |     | DATA0 |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9      | 8      | 7      | 6     | 5     | 4   | 3   | 2     | 1  | 0  |

|          |    |    |    |    |    |        | MOD    | DE     | Y_RST | ved   | G_S | RT  | RR    |    |    |
|          |    |    |    |    |    |        | E      |        |       |       | W   |     |       |    |    |

| Bit     | Name       | Access         | Description  | Reset value  |   |
|---------|------------|----------------|--|--|---|
| [31:26] | Reserved   | RO             | Reserved   | 0  |   |
| [25:18] | DATA1[7:0] | RO             | Data byte 1.   | X  |   |
| [17:10] | DATA0[7:0] | RO             | Data byte 0.   | X  |   |
| [9:8]   | FIX_11     | RO             | Fixed at 11.   | 11b  |   |
| 7       | USE<br>R   | STATR_M<br>ODE | RO   | Power-on startup mode:<br>1: Startup from BOOT area;<br>0: Startup from user area. | 1 |
| [6:5]   |            | RST_MOD<br>E   | RO   | Configure byte reset delay time.   | X |
| 4       |            | STANDY_<br>RST | RO   | The system is reset and controlled in standby mode, active low.                    | X |
| 3       |            | Reserved       | RO   | Reserved   | X |
| 2       |            | IWDG_SW        | RO   | Independent watchdog (IWDG) hardware enable bit, active low.                       | 1 |
| 1       | RDPRT      | RO             | Read protection status.<br>1: Indicates that the current read protection of flash memory is valid. | 1  |   |
| 0       | OBERR      | RO             | Option byte error.<br>1: Indicates that the option byte does not match its inverse code.           | 0  |   |

### 18.3.8 Write Protect Register (FLASH\_WPR)

Offset address: 0x20

|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

| Bit    | Name      | Access | Description   | Reset value |
|--------|-----------|--------|---|-------------|
| [31:0] | WPR[31:0] | RO     | Flash write protection status.<br>1: Write protection invalid;<br>0: Write protection valid.<br>Each bit represents 2K bytes (8 pages) to store write-protected status. | X           |

Note: The WPR is loaded from the user option byte area after the system is reset.

### 18.3.9 Extended Key Register (FLASH\_MODEKEYR)

Offset address: 0x24

| Bit    | Name           | Access | Description  | Reset value |
|--------|----------------|--------|--|-------------|
| [31:0] | MODEKEYR[31:0] | WO     | Enter the following sequence to unlock quick programming / erase mode.<br>KEY1 = 0x45670123;<br>KEY2 = 0xCDEF89AB.<br>(Note: FLASH needs to be unlocked first) | X           |

### 18.3.10 BOOT Key Register (FLASH\_BOOT\_MODEKEYP)

Offset address: 0x28

| Bit    | Name           | Access | Description   | Reset value |
|--------|----------------|--------|---|-------------|
| [31:0] | MODEKEYR[31:0] | WO     | Enter the following sequence to unlock the BOOT area.<br>KEY1 = 0x45670123;<br>KEY2 = 0xCDEF89AB. | X           |

## 18.4 Flash Memory Operation Flow

### 18.4.1 Read Operations

With direct addressing in the general address space, any read operation of 8/16/32-bit data can access the contents of the flash module and get the corresponding data.

### 18.4.2 Unlock the Flash Memory

After a system reset, the flash controller (FPEC) and FLASH\_CTLR registers are locked and inaccessible. The flash controller module can be unlocked by writing a sequence to the FLASH\_KEYR register.

Unlock sequence.

- 1) Write KEY1 = 0x45670123 to the FLASH\_KEYR register (step 1 must be KEY1).
- 2) Write KEY2 = 0xCDEF89AB to FLASH\_KEYR register (step 2 must be KEY2).

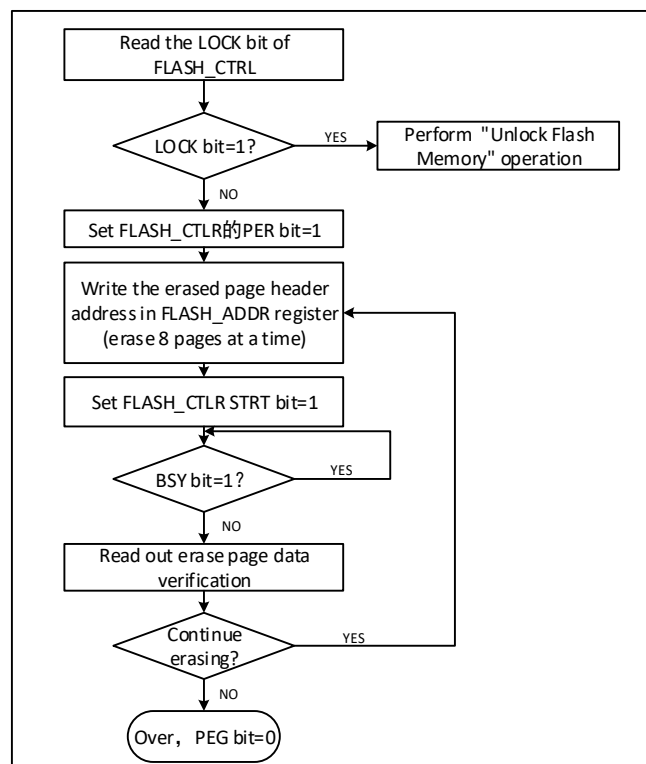

The above operations must be executed sequentially and consecutively, otherwise they are error operations and will lock the FPEC module and FLASH\_CTLR registers and generate bus errors until the next system reset.

The flash memory controller (FPEC) and FLASH\_CTLR registers can be locked again by setting the "LOCK" bit of the FLASH\_CTLR register to 1.

### 18.4.3 Main Memory Standard Erase

Flash memory can be erased by standard page (1K bytes) or by whole chip.

Figure 18-1 FLASH Page Erase

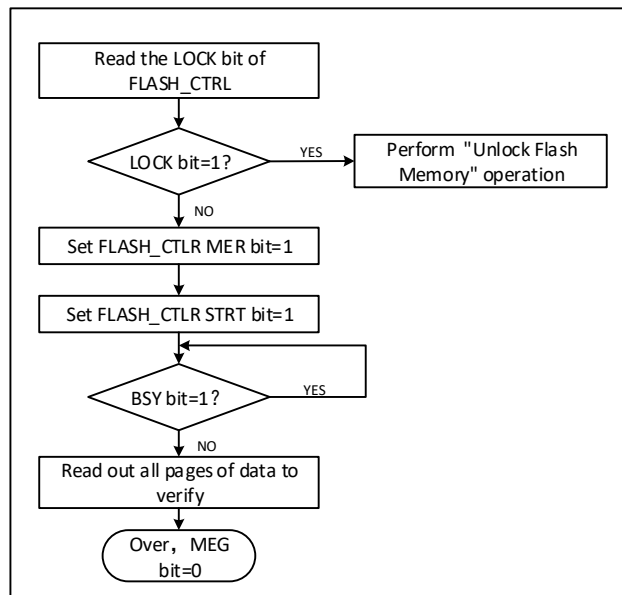

- 1) Check the FLASH\_CTLR register LOCK bit, if it is 1, you need to perform the "unlock flash" operation.
- 2) Set the per bit of the FLASH\_CTLR register to '1'percent, and turn on the standard page erase mode.
- 3) Write the header address of the selected erasure to the FLASH\_ADDR register.
- 4) Set the STRT bit of the FLASH\_CTLR register to '1'percent, and start an erase operation.
- 5) Waiting for the BSY bit to change to '0' or the EOP bit of the FLASH\_STATR register to be '1' means the erasure

is over, and the EOP bit is cleared to 0.

- 6) Read the data of the erasure page for verification.
- 7) Continue the standard page erasure by repeating the 3-5 steps to end the erase to clear the PEG bit 0.

*Note: After erasing successfully, read the word-0xFF.*

Figure 18-2 FLASH whole chip erase

- 1) Check the FLASH\_CTRL register LOCK bit, if it is 1, you need to perform the "unlock flash" operation.
- 2) Set the MER bit of the FLASH\_CTRL register to '1', and turn on the whole chip erase mode.
- 3) Set the STRT bit of the FLASH\_CTRL register to '1' to start the erase action.
- 4) Waiting for the BSY bit to change to '0' or the EOP bit of the FLASH\_STATR register to be '1' means the erasure is over, and the EOP bit is cleared to 0.
- 5) Read the data of the erasure page for verification.
- 6) Clear the MER bit 0.

#### 18.4.4 Fast Programming Mode Unlocking

Fast programming mode operation can be unlocked by writing a sequence to the FLASH\_MODEKEYR register. After unlocking, the FLOCK bit of FLASH\_CTRL register will be cleared to 0, indicating that fast erase and programming operations can be performed. The FLASH\_CTRL register is locked again by software setting the "FLOCK" bit to 1.

Unlock sequence.

- 1) Write KEY1 = 0x45670123 to the FLASH\_MODEKEYR register.
- 2) Write KEY2 = 0xCDEF89AB to FLASH\_MODEKEYR register.

The above operations must be performed sequentially and consecutively, otherwise they are wrong operations will be locked and cannot be unlocked again until the next system reset.

*Note: Fast programming operation requires unlocking the "LOCK" and "FLOCK" layers.*

#### 18.4.5 Main Memory Fast Programming

Fast programming by page (256 bytes).

- 1) Check the LOCK bit of FLASH\_CTRL register, if it is '1', you need to execute the "Unlock Flash" operation.

- 2) Check the FLOCK bit of FLASH\_CTLR register. If it is '1', you need to perform a "Fast programming mode unlock" operation.
- 3) Check the BSY bit of the FLASH\_STATR register to confirm that there are no other programming operations in progress.
- 4) Set the FTPG bit of FLASH\_CTLR register to enable the fast programming mode function.
- 5) Set the BUFRST bit of FLASH\_CTLR register to perform the operation of clearing the internal 256-byte buffer.
- 6) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to be '1' to indicate the end of clearing, and clear the EOP bit to 0.
- 7) Write data to a FLASH address in a 32-bit manner, such as  
\* (uint32\_t\*) 0x8000000 = 0x12345678;
- 8) Then set the BUFLOAD bit of the FLASH\_CTLR register and perform the load into the cache.
- 9) Wait for the WR\_BSY of the FLASH\_STATR register to be '0', and write the next data.
- 10) Repeat steps 7-9 a total of 4 times to load all 16 bytes of data into the buffer (4 rounds of operation addresses should be consecutive).
- 11) Write the first address of the fast programming page to the FLASH\_ADDR register.
- 12) Set the STRT bit of FLASH\_CTLR register to '1' to start a fast page programming action.
- 13) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to be '1' to indicate the end of programming, and clear the EOP bit to 0.
- 14) Query FLASH\_STATR register to see if there is an error, or read the programmed address data checksum.
- 15) Continue the Quick Page programming can repeat steps 5-14 and end the programming to clear the FTPG bit to 0.

#### 18.4.6 Main Memory Fast Erase

Fast Erase erases by page (256 bytes).

- 1) Check the LOCK bit of FLASH\_CTLR register, if it is 1, you need to execute the "Unlock Flash" operation.
- 2) Check the FLASH\_CTLR register FLOCK bit, if it is 1, you need to execute the "Fast programming mode unlock" operation.
- 3) Check the BSY bit of the FLASH\_STATR register to confirm that there are no other programming operations in progress.
- 4) Set the FTER bit of FLASH\_CTLR register to '1' to enable the fast page erase (256 bytes) mode function.
- 5) Write the first address of the fast erase page to the FLASH\_ADDR register.
- 6) Set the STRT bit of FLASH\_CTLR register to '1' to initiate a fast page erase (256 bytes) action.
- 7) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to be '1' to indicate the end of erase, and clear the EOP bit to 0.
- 8) Query FLASH\_STATR register to see if there is an error, or read the erase page address data checksum.
- 9) Continue fast page erase can repeat steps 5-8, end erase will FTER bit clear 0.

*Note: After erasing successfully, read the word-0xFF.*

Fast Erase erases by page (32 bytes).

- 1) Check the LOCK bit of FLASH\_CTLR register, if it is 1, you need to execute the "Unlock Flash" operation.
- 2) Check the FLASH\_CTLR register FLOCK bit, if it is 1, you need to execute the "Fast programming mode unlock" operation.
- 3) Check the BSY bit of the FLASH\_STATR register to confirm that there are no other programming operations in progress.
- 4) Set the FTER bit of FLASH\_CTLR register to '1' to enable the fast page erase (32 bytes) mode function.

- 5) Write the first address of the fast erase page to the FLASH\_ADDR register.
- 6) Set the STRT bit of FLASH\_CTLR register to '1' to initiate a fast page erase (32 bytes) action.
- 7) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to be '1' to indicate the end of erase, and clear the EOP bit to 0.
- 8) Query FLASH\_STATR register to see if there is an error, or read the erase page address data checksum.
- 9) Continue fast page erase can repeat steps 5-8, end erase will BER32 bit clear 0.

*Note: After erasing successfully, read the word-0xFF.*

## 18.5 User Option Bytes

The user option bytes are fixed in the FLASH and will be reloaded into the corresponding register after the system is reset, and the user can erase and program at will. The user option bytes block with a total of 8 bytes (4 bytes for write protection, 1 byte for read protection, 1 byte for configuration options, and 2 bytes for storing user data), and each bit has its own inverse code bit for checking during loading. The information structure and meaning of the option bytes are described below.

Table 18-3 32-bit option byte format division

| [31:24]                             | [23:16]             | [15:8]                              | [7:0]               |
|-------------------------------------|---------------------|-------------------------------------|---------------------|
| Option bytes byte 1<br>inverse code | Option bytes byte 1 | Option bytes byte 0<br>inverse code | Option bytes byte 0 |

Table 18-4 User option byte information structure

| Address<br>Bit | [31:24] | [23:16] | [15:8] | [7:0] |
|----------------|---------|---------|--------|-------|
| 0x1FFFF800     | nUSER   | USER    | nRDPR  | RDPR  |
| 0x1FFFF804     | nData1  | Data1   | nData0 | Data0 |
| 0x1FFFF808     | nWRPR1  | WRPR1   | nWRPR0 | WRPR0 |
| 0x1FFFF80C     | nWRPR3  | WRPR3   | nWRPR2 | WRPR2 |

| Name/Byte |       |            | Description   | Reset value |
|-----------|-------|------------|---|-------------|
| RDPR      |       |            | Read protection control bit and configure whether the code in the flash memory can be read.<br>0xA5: If this byte is 0xA5 (nRDP must be 0x5A), it indicates that the current code is in an unread-protected state and can be read;<br>Other values: Indicates the code read protection status, unreadable, 0-7 pages (2K) will be automatically write-protected, not controlled by WRPR0. | 0xA5        |
| USER      | [7:6] | Reserved   | Reserved  | 11b         |
|           | 5     | START_MODE | Power-on startup mode:<br>1: Boot from BOOT area<br>0: Boot from user area  | 1           |
|           | [4:3] | RST_MOD    | PD7 alternate as external pin reset.  | 10b         |

|               |               |   |                 |
|---------------|---------------|---|-----------------|
|               | E<br>[1:0]    | 00: Ignoring pin states within 128us after turning on the alternate function.<br>01: Ignoring pin states within 1ms after turning on the alternate function.<br>10: Ignoring pin states within 12ms after turning on the alternate function.<br>11: Alternate function off, PD7 for I/O function.   |                 |
| 2             | STANDYR<br>ST | System reset control in Standby mode:<br>1: Not enabled, does not reset when entering Standby mode system;<br>0: Enabled, generates a system reset when entering Standby mode.  | 1               |
| 1             | Reserved      | Reserved  | 1               |
| 0             | IWDG_SW       | Independent watchdog (IWDG) hardware enable configuration.<br>1: IWDG is opened by software, but hardware is not allowed;<br>0: The IWDG is turned on by the hardware itself (since the clock of the IWDG is provided by the LSI, the LSI will turn on automatically).<br><i>Note: If the core stops in debug mode, the watchdog hardware will fail.</i>  | 1               |
| Data0–Data1   |               | Stores 2 bytes of user data.  | 0xFFFF          |
| WRPR0 - WRPR3 |               | Write protection control bit. Each bit is used to control the write protection status of 2 sectors (1K bytes / sector) in the main memory:<br>1: Disable write protection<br>0: Enable write protection.<br>4 bytes are used to protect a total of 65K bytes of main memory.<br>WRP0: Sector 0-15 storage write protection control;<br>WRP1: Sector 16-31 storage write protection control;<br>WRP2: Sector 32-47 storage write protection control;<br>WRP3: Bit 0-6 provides write protection for sector 48-61; bit 7 provides write protection for sector 62 (3328 bytes of system memory). | 0xFFFFFFFF<br>F |

### 18.5.1 User Option Bytes Unlocking

The user option bytes operation can be unlocked by writing a sequence to the FLASH\_OBKEYR register. After unlocking, the OBWRE bit of FLASH\_CTLR register will be set to 1, indicating that the user option bytes can be erased and programmed. It can be locked again by clearing the "OBWRE" bit of FLASH\_CTLR register to 0 by software.

Unlock sequence.

- 1) Write KEY1 = 0x45670123 to FLASH\_OBKEYR register.

2) Write KEY2 = 0xCDEF89AB to FLASH\_OBKEYR register.

*Note: User-option bytes operation requires unlocking the "LOCK" and "OBWRE" layers.*

### 18.5.2 User Option Bytes Programming

- 1) Check the LOCK bit of FLASH\_CTLR register, if it is 1, you need to execute the "Unlock Flash" operation.
- 2) Check the FLASH\_CTLR register FLOCK bit. If it is '1', you need to perform a "Fast programming mode unlock" operation.
- 3) Check the BSY bit of the FLASH\_STATR register to verify that there are no other programming operations in progress.
- 4) Set the FTPG bit of the FLASH\_CTLR register to '1' to enable fast page programming mode.
- 5) Set the BUFRST bit of the FLASH\_CTLR register and perform the operation of clearing the internal 256byte cache.
- 6) Waiting for the BSY bit to change to '0' or the EOP bit of the FLASH\_STATR register to be '1' means that the cleanup is over, and the EOP bit is cleared to 0.
- 7) Write data to a FLASH address in a 32-bit manner, such as  
`*(uint32_t*)0x1FFFF804= 0x5AA55AA5;`
- 8) Then set the BUFLOAD bit of the FLASH\_CTLR register and perform the load into the cache.
- 9) Wait for the WR\_BSY of the FLASH\_STATR register to be '0'percent, and write the next data.
- 10) Repeat steps 5-9 for 4 times to load 256 bytes of data into the cache (the addresses of the main 16 rounds of operations should be continuous).
- 11) Write the first address of the quick programming page to the FLASH\_ADDR register.
- 12) Set the STRT bit of the FLASH\_CTLR register to '1' to start fast page programming.
- 13) Waiting for the BSY bit to change to '0' or the EOP bit of the FLASH\_STATR register to '1' means that a quick page programming is completed and the EOP bit is cleared to 0.
- 14) Query the FLASH\_STATR register to see if there are errors, or read the programming address data check.
- 15) To continue fast page programming, you can repeat steps 5-14 to end programming to clear the FTPG bit 0.

*Note: When "read protected" in the modified selection word is changed to "unprotected" state, an entire erase main storage area operation is automatically performed. If you modify a selection other than read Protection, the whole erase operation will not occur.*

### 18.5.3 User Option Bytes Erasure

Directly erase the entire 256-byte user option bytes area.

- 1) Check the LOCK bit of FLASH\_CTLR register, if it is 1, you need to execute the "Unlock Flash" operation.
- 2) Check the BSY bit of the FLASH\_STATR register to confirm that there is no programming operation in progress.
- 3) Check the OBWRE bit of FLASH\_CTLR register, if it is 0, it is necessary to execute the operation of "user option bytes unlock".
- 4) Set the OBER bit of FLASH\_CTLR register to '1', after that set the STAT bit of FLASH\_CTLR register to '1' to enable the user option bytes erase.
- 5) Wait for the BSY bit to become '0' or the EOP bit of FLASH\_STATR register to be '1' to indicate the end of erase, and clear the EOP bit to 0
- 6) Read and erase the address data checksum.
- 7) End to clear the OBER bit to 0.

### 18.5.4 Remove Read Protection

Whether the flash memory is read-protected or not is determined by the word selected by the user. Read the FLASH\_OBR register. When the RDPRT bit is '1', it indicates that the current flash memory is in read-protected state, and the flash operation is protected by a series of read-protected states. The process of unprotecting read is as follows:

- 1) Erase the entire user option byte area, read the protection field RDPR, and read protection is still in effect.
- 2) The user chooses the word to program and writes the correct RDPR code 0xA5 to remove the read protection of the flash memory. (This step will first cause the system to automatically erase the entire piece of flash memory.)
- 3) A power-on reset is performed to reload the option bytes (including the new RDPR code), and the read protection is removed.

### 18.5.4 Remove Write Protection

Whether the flash memory is write-protected or not is determined by the user option bytes. Read the FLASH\_WPR register, each bit represents 2K bytes of flash space, when the bit is '1' for non-write-protected state, for '0' for write-protected. The process of unprotecting a write is as follows:

- 1) Erases the entire user option bytes area;
- 2) Write the correct RDPR code 0xA5 to allow read access;
- 3) The system is reset, the option bytes are reloaded (including the new WRPR [3:0] bytes), and the write protection is removed.

## Chapter 19 Electronic Signature (ESIG)

*The module described in this chapter is suitable for the full range of CH32V00X microcontrollers.*

The electronic signature contains chip identification information: flash area capacity and unique identity. It is burned by the manufacturer to the system storage area of the memory module when it leaves the factory and can be read through SWD (SDI) or application code.

### 19.1 Function Description

Flash area capacity: indicates the size that the current chip user application can use.

Unique identity: 96-bit binary code, which is unique to any microcontroller and can only be read and accessed by the user. This unique identification information can be used as the security password of the microcontroller (product), add and decrypt key, product serial number, etc., to improve the system security mechanism or identify information. All of the above can be read and accessed according to the 8-16-32 bit.

### 19.2 Register Description

Table 19-1 ESIG-related registers list

| Name            | Offset address | Description             | Reset value |
|-----------------|----------------|-------------------------|-------------|
| R16_ESIG_FLACAP | 0x1FFFF7E0     | Flash Capacity Register | 0xFFFF      |
| R32_ESIG_UNIID1 | 0x1FFFF7E8     | UID Register 1          | 0xFFFFFFFF  |
| R32_ESIG_UNIID2 | 0x1FFFF7EC     | UID Register 2          | 0xFFFFFFFF  |
| R32_ESIG_UNIID3 | 0x1FFFF7F0     | UID Register 3          | 0xFFFFFFFF  |

#### 19.2.1 Flash Capacity Register (ESIG\_FLACAP)

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

| Bit    | Name         | Access | Description   | Reset value |
|--------|--------------|--------|---|-------------|
| [15:0] | F_SIZE[15:0] | RO     | Flash capacity in Kbyte.<br>Example: 0x0080 = 128 K bytes | X           |

#### 19.2.2 UID Register (ESIG\_UNIID1)

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

| Bit    | Name       | Access | Description           | Reset value |
|--------|------------|--------|-----------------------|-------------|
| [31:0] | U_ID[31:0] | RO     | The 0-31 bits of UID. | X           |

### 19.2.3 UID Register (ESIG\_UNIID2)

| Bit    | Name        | Access | Description            | Reset value |
|--------|-------------|--------|------------------------|-------------|
| [31:0] | U_ID[63:32] | RO     | The 32-63 bits of UID. | X           |

### 19.2.4 UID Register (ESIG\_UNIID3)

| Bit    | Name        | Access | Description              | Reset value |
|--------|-------------|--------|--------------------------|-------------|
| [31:0] | U_ID[95:64] | RO     | The 64-95 digits of UID. | X           |

## Chapter 20 Extended Configuration

### 20.1 Extended Configuration

The system provides an EXTEN extension configuration unit (EXTEN\_CTR register). The unit uses a HB clock and performs a reset action only when the system is reset. It mainly includes the following extended control bit functions:

- 1) Lock-up function monitoring: If the LKUPEN field is enabled, the Lock-up situation monitoring of the system will be turned on. In case of Lock-up, the system will reset the LKUPRST field by software and set the LKUPRST field to 1. After reading, you can write 1 to clear this flag.
- 2) DMA reuse of TIM2: The updated DMA channel can be shared between the DMA request of TIM2 channel 4 and the updated DMA request by configuring the TIM2\_DMA\_REMAP bit.

### 20.2 Register Description

Table 20-1 EXTEND-related registers list

| Name          | Access address | Description                         | Reset value |
|---------------|----------------|-------------------------------------|-------------|
| R32_EXTEN_CTR | 0x40023800     | Configure Extended Control Register | 0x00000400  |

#### 20.2.1 Configure Extended Control Register (EXTEND\_CTR)

Offset address: 0x00

|          |    |    |    |    |    |    |    |                 |                |          |    |    |    |    |                        |  |

## Chapter 21 Debug Support (DBG)

### 21.1 Main Features

This register allows the MCU to be configured in the debug state. It includes:

- Independent Watchdog (IWDG) enabled counters
- Window Watchdog (WWDG) enabled counters
- Timer1 enabled counters
- Timer2 enabled counters

### 21.2 Register Description

#### 21.2.1 Debug MCU Configuration Register (DBGMCU\_CR)

Address: 0x7C0 (CSR)

|          |           |           |           |          |    |    |           |           |          |    |    |    |    |         |          |       |

| 2     | STANDBY  | RW | Debug standby mode bit.<br>1: (HCLK on) The digital circuitry section is not powered down, and the FCLK and HCLK clocks are clocked by the internal RL oscillator. Alternatively, the microcontroller exits STANDBY mode and reset by generating a system reset is the same.<br>0: (HCLK off) The entire digital circuitry section is powered down.<br>From the software point of view, exiting STANDBY mode is the same as a reset (Except that some status bits indicate that the microcontroller has just exited from STANDBY state). | 0 |
| 1     | Reserved | RW | Reserved   | 0 |
| 0     | SLEEP    | RW | Debug sleep mode bit.<br>1: (HCLK on) In Sleep mode, both FCLK and HCLK clocks are provided by the originally configured system clock.<br>0: (HCLK off) In Sleep mode, FCLK is provided by the originally configured system clock, and HCLK is off. Since Sleep mode does not reset the configured clock system, the software does not need to reconfigure the clock system when exiting from sleep mode.  | 0 |
